CHAPTER SIX

DEMOGRAPHY

THE POPULATION OF AUSTRALIA

By June 1986 the estimated resident population of Australia passed the 16 million mark, reaching 16,250,000 by mid-1987. Despite the continuous growth in population throughout the years since European settlement, the rate at which the growth has occurred has varied considerably. This chapter traces the history of population growth in the last two hundred years and the contributions made by natural increase and migration. The statistics in this chapter are derived from population censuses, registers of births, deaths and marriages, court records of divorces and other records such as passenger cards from international travel and family allowance transfers.

Estimates of the Aboriginal population at the time of European settlement vary considerably but recent archaeological finds suggest that a population of 750,000 could have been sustained. Since European settlement, the Aboriginal population has suffered considerable decline, although to what extent is unclear. Section 127 of the Constitution required the exclusion of Aboriginals when estimating the population of the Commonwealth or of a State or other part of the Commonwealth. This provision was repealed with the proclamation of the *Constitution Alteration (Aboriginals) Act 1967* and, since 10 August 1967, population and vital statistics have included full-blooded Aboriginals. Additionally, estimates back to 30 June 1961 have been revised to include Aboriginals.

Size and growth of the Australian population

AUSTRALIAN POPULATION GROWTH SINCE EUROPEAN SETTLEMENT, TIME ELAPSED BETWEEN SUCCESSIVE MILLIONS, 1788-1986

Population (a)	Year attained	Interval since previous million attained		Average annual rate of population growth
		Years	Months	Per cent
One million1858	70		..
Two million1877	19		3.7
Three million1889	12		3.4
Four million1905	16		1.8
Five million1918	13		1.7
Six million1925	7		2.6
Seven million1939	14		1.1
Eight million1949 (November)	10		1.3
Nine million1954 (August)	4	9	2.5
Ten million1959 (March)	4	7	2.3
Eleven million1963 (December)	4	9	2.0
Eleven million1963 (October)
Twelve million1968 (June)	4	8	1.9
Thirteen million1972 (September)	4	3	1.9
Thirteen million1971 (March)
Fourteen million1976 (March)	5	—	1.5
Fifteen million1981 (October)	5	7	1.2
Sixteen million1986 (June)	4	8	1.3

(a) For population estimation purposes, estimates prior to 1961 exclude full-blood Aboriginals. Estimates for dates earlier than the 1971 Census are based on census counts (actual location) and contain no adjustments for census under-enumeration. Estimates for 1971 and subsequent years are estimated resident population. The attainment of the eleventh million is shown both excluding and including full-blood Aboriginals and the attainment of the thirteenth million is shown both on an actual location basis and an estimated resident population basis.

POPULATION INCREASE AND COMPONENTS OF INCREASE, 1861 - 1985

NOTE: Full-blood Aboriginals excluded prior to 1962. Deaths and migration of troops excluded 1939-1947. Commencing 1976, net migration includes an adjustment for 'category jumping', whose duration of stay (category) differs from their stated intention at the time of arrival or departure.

The population of Australia now exceeds 16 million. The increase from 15 to 16 million took approximately 4 years and 10 months, compared with the 70 years it took to reach the first million, achieved in 1858, and the 19 years to reach the second million in 1877. The shortest period for a population growth of 1 million was 4 years and 3 months, when the population reached 13 million in 1972. The table above shows the growth of the Australian population since European settlement and clearly indicates the variety in growth rates.

Since 1788, four periods in particular experienced high rates of growth. The first of these occurred during the gold rush of the 1850s, when the population doubled from 0.5 million in 1852 to 1 million in 1858. Subsequent economic diversification and pastoral expansion led to the second period of rapid population growth during the prosperity of the 1850s, when the population increased by 1 million in the 12 years between 1877 and 1889, with average annual growth rates of 3.4 per cent.

Both the third and fourth phases of rapid growth occurred during the present century, after World War I and World War II. Between 1918 and 1925, the population grew by 1 million, with average annual growth rates rising from 1.7 per cent in the pre-war period to 2.6 per cent during 1918–25, before falling to 1.1 per cent during the economic depression of the 1930s. The boom in population growth after World War II continued until the early 1970s, with annual growth rates averaging 2.1 per cent between 1946 and 1970. After reaching 8 million in 1949 the addition of each successive million to the population took less than 5 years and, in 1972, stood at 13 million.

Until the 1860s, net migration was the major component of population growth, but since that time natural increase has been the dominant factor, providing 69.3 per cent of the increase between 1861 and 1985. Nevertheless, the importance of natural increase to population growth was greater during the period prior to World War II, contributing 83.3 per cent of total increase between 1901 and 1945, but only 62.4 per cent between 1946 and 1985.

Changes to the level of net migration have influenced the rate of population growth. Periods of rapid growth have included a large net migration component, 73.0 per cent in the 1850s, 40.1 per cent in the 1880s, 31.0 per cent in the first half of the 1920s and 39.1 per cent between 1946 and 1970. Conversely, the rate of population increase has fallen when net migration levels have dropped—during the economic depressions of the 1890s and 1930s, both World War I and World War II and, more recently, during the recession of the 1970s.

During the 1970s, population growth slowed as both net migration and natural increase declined, with average annual growth rates falling from 1.9 per cent at the end of the 1960s to 1.2 per cent between 1976–81. Natural increase stabilised more recently, while net migration generally increased and average annual growth rates have increased slightly in the 1980s to 1.3 per cent.

Population distribution

The population of Australia is concentrated in capital and other major cities, mainly on the south and east coasts of the continent (for details, see the coloured population density map). This results from a variety of factors including climate, physical characteristics of the continent, changing agricultural practices, exploitation of mineral resources and personal preference.

Historically the Australian colonies relied on shipping as a major form of transportation, both between themselves and with Britain. Subsequent economic developments throughout the 19th century, such as the development of an export economy based on wool, gold and wheat, together with a continuing dependence on imports, ensured the ascendancy of capital cities located on or close to coastal ports.

The tendency of settlement to concentrate along the coastal strip was exacerbated initially by difficulties in traversing the coastal range of New South Wales. The arid nature of much of inland Australia militated against the viability of small-scale intensive farming techniques beyond the coastal areas.

In 1850, some 80.0 per cent of the population was estimated to be living in the older settlements of New South Wales and Tasmania, with most of the remaining population residing in South Australia. However, the gold discoveries of the 1850s attracted a wave of overseas migrants to the south-eastern corner of the continent, particularly to the Victorian goldfields. This pattern of settlement has continued since that time. At the 1986 Census, for instance, 62.1 per cent of the Australian population were living in New South Wales, Victoria

and the Australian Capital Territory. The Australian Capital Territory had the highest population density of the States and Territories at 107.9 persons per square kilometre, followed by Victoria at 18.3 and New South Wales at 6.9. These figures contrast sharply with densities in Western Australia and the Northern Territory of 0.6 and 0.1 persons per square kilometre respectively.

(a) Figures prior to 1971 are census counts. The estimates from June 1971 for each State and Territory are estimated resident populations at census dates. Figures prior to 1966 exclude full-blood Aboriginals. (b) Previously included with New South Wales. (c) Previously included with South Australia.

Discovery and exploitation of mineral resources have not only encouraged immigration from overseas, but have affected the distribution of population internally. Discoveries of gold in Queensland in the 1870s and Western Australia in the 1890s encouraged interstate migration from the south-eastern States, and particularly from Victoria and South Australia during the economic recession of the 1890s. This pattern of interstate migration to Queensland and Western Australia was repeated during the 1960s mineral boom in those States. However, the rank order of the States by population numbers in 1901 (New South Wales, Victoria, Queensland, South Australia, Western Australia and Tasmania) remained the same until 1982 when the population of Western Australia surpassed that of South Australia.

In June 1983, 69.0 per cent of the Australian population lived in the combined State capitals, the national capital and Darwin, and four other major cities of 100,000 or more persons (capital city statistical divisions and statistical districts). Although urban populations are not strictly comparable due to changes in classification, the proportions of New South Wales and Victorian populations residing in the metropolitan areas of Sydney and Melbourne at the 1871 Census were 26.7 per cent and 28.9 per cent respectively, while one hundred years later these proportions were estimated to be 63.8 per cent and 71.5 per cent.

Between 1921 and 1947, 71.1 per cent of the intercensal population increase was within capital cities, and this proportion increased to 81.0 per cent between 1947 and 1981. With the continuing development of urban industrialisation in the 20th century, capital cities have been the consistent choice for settlement of the majority of overseas immigrants, as well as receiving centres in the general internal trend towards rural to urban migration which persisted until recent times. This trend was already established by the 1890s as changing technological and marketing conditions associated with agricultural practices reduced the potential for labour force absorption to below the level of natural increase. By the 1930s, the population in rural areas had declined, not only as a proportion of the total population, but also in absolute numbers.

(a) Census counts by State of enumeration. Excludes full-blood Aboriginals prior to 1961. (b) Urban and rural proportions do not add up to 100 per cent as the proportion of migratory population is not included.

Between the 1976 and 1981 Censuses, however, the proportion of the population living in rural areas actually increased from 13.9 per cent to 14.2 per cent, while the proportion of State populations living in the capital cities of Sydney, Melbourne, Brisbane and Adelaide has declined slightly since 1976. Parallel with this has been an emerging trend since the 1970s towards selective rapid growth of smaller coastal towns in Queensland, New South Wales and Victoria which have favoured the development of retirement, recreation and tourist amenities.

POPULATION AGE PYRAMIDS, AUSTRALIA

1881 CENSUS

1933 CENSUS

1981 CENSUS

During the early years of European settlement the age/sex profile of the non-Aboriginal population was highly irregular, consisting predominantly of young adult males. Although efforts were made from the 1830s to assist families and young single women to migrate to Australia, the gold discoveries of the 1850s and the high rates of economic growth which followed until the late 1880s encouraged the continuance of migration in which males predominated. Net migration figures from 1861 to 1900 show that males outnumbered females almost 2 to 1.

Throughout the latter half of the 19th century, however, rises in natural increase ensured a decline in the overall sex ratio, particularly among the younger age groups. At the 1881 census, for example, the overall sex ratio was 121 males for every 100 females but stood at 143 for those aged 25 and over and 103 for those under 25 years. The sex ratio continued to decline until after World War II when the male dominated overseas migration intake reversed this trend.

While the overall sex ratio remained around 102 during the 1950s and 1960s, for the 15–44 year age group the ratio was 106 or more. Both began to fall during the 1970s as migration rates declined and the composition of the migrant intake changed. By 1981, the female population of Australia exceeded the male population, with the sex ratio indicating a definite female bias in the older age groups.

Comparison of the 1881 and 1981 age pyramids clearly shows the extent to which the Australian population has 'aged' during the last 100 years. At the 1881 census, the median age was 20.8 years, by 1981 it had reached 29.6 years and it is predicted to increase to between 34.3 and 34.9 years by 2001. Similarly, the proportion of the population aged 65 years and over has increased from 2.2 per cent in 1881 to 9.7 per cent in 1981 while the proportion aged less than 15 years fell from 38.9 per cent to 25.0 per cent in the same period.

The change in the age structure over the last century has been due to improvements in life expectancy, and declines in the birth rate, both of which have increased the median age of the population. Declines in fertility are particularly indicated by the undercutting at the base of the age pyramids for 1933 and 1981 in the under 5 age group.

Nevertheless, the trend towards ageing of the population has not been uniform throughout the last century. High levels of migration and rising numbers of births during the 1950s and 1960s both contributed to a temporary decline in the median age, from 30.7 years in 1947 to 27.5 years in 1971, while the proportion aged under 15 increased from 25.1 per cent in 1947 to 30.2 per cent in 1961, as indicated in the previous table.

Rapid declines in fertility and, to a lesser extent, mortality, have contributed significantly to the ageing of the population in the 1970s and 1980s. However, the increase in migration flows as well as emphasis on family migration, has tended to delay this process.

Marital status

Marriage laws were first enacted in the Australian colonies from the late 1830s. Following Federation the Commonwealth Parliament was given power to legislate concerning marriage, divorce and matrimonial causes. Subsequent amendments were made to the Marriage Act in 1961.

The Marriage Act makes provision, on a uniform basis, in respect of prohibited relations, other grounds for void marriages, legitimation, marriage overseas and pre-marital education. Dissolution of marriage was covered by separate State and Territory legislation until 1961 when the *Matrimonial Causes Act 1959–66* came into operation. The *Family Law Act 1975* which replaced the *Matrimonial Causes Act*, came into operation on 5 January 1976 and provides for a single ground for divorce—irretrievable breakdown of marriage—and for nullity of marriage on the ground that the marriage is void.

A major factor influencing marriage rates and therefore the marital status of the population in the first century of European settlement was the availability of partners and, in particular, the sex ratio at marriageable ages.

At the 1851 census, the New South Wales Statistician reported that 77 per cent of women aged 20 and over in the colony were married, compared with 57 per cent in Great Britain. However, proportions for men aged 20 and over showed 49 per cent married in New South Wales compared with 62 per cent in Great Britain. By the time of the 1881 census, the proportion of males aged 15 and over ever-married in Australia was 47 per cent compared with 63 per cent of women. The proportion of women never-marrying was lower than for

PROPORTION OF NEVER MARRIED PERSONS, CENSUS DATES, AUSTRALIA

men in every age group, with only 6.6 per cent of women remaining unmarried at ages 40–44 compared with 30.6 per cent of men.

Towards the end of the 19th century, the pattern of high incidence of marriage for women began to change. A number of factors combined to reduce the availability of marriage partners for women, particularly in south-east Australia. Overseas migration virtually ceased during the economic depression of the 1890s and sex ratios for the 15–24 year-olds began to fall, the numbers of males and females being close to equal by 1901. Moreover, the geographical distribution of the sexes differed, with men leaving the south-eastern States in search of work, particularly in the Western Australian goldfields. By 1901 the sex ratio for the 15–24 year-olds was below 100 in Victoria, New South Wales and South Australia, varying throughout Australia between 93 in Victoria to 144 in Western Australia.

In the years following the 1881 census, the proportion of males who had never married by ages 40–44 declined continually at every census date to about 10 per cent in 1981. For women of the same age group, however, the proportions who never married increased until the 1921 Census, peaking at 17.7 per cent, and did not decline to the low rates of 1881 until 1961. The overall extent of the decline in proportions never-married during the last century has thus been greater for men than for women.

Part of the decline in proportions of never married following the 1933 Census can be accounted for by marriages deferred during the economic depression, but more importantly, there was a shift to marrying at an earlier age.

By 1971, only 10 per cent of men and 5 per cent of women aged 40–44 had never married. Since the 1970s there has been a reversal of these previous trends. The increasing proportions of never married for both sexes in the younger age groups since 1971 can be seen in the above graph. In the decade between 1971 and 1981 there has been an increase in the proportions of never married in the 20–24 year age group by 13 percentage points for males and 18 percentage points for females. At the time of the 1981 Census, the proportions never married had increased for both sexes at all ages between 15 and 35 years, suggesting that there is likely to be an overall increase in the proportions who will ultimately never marry.

Two changes are noticeable within the distribution of the ever-married population. Firstly, there has been a gradual increase in the proportion of divorced persons since 1901 with a more noticeable increase since 1976 following reforms to the Family Law Act in 1975 (see also Vital Statistics Section on divorce). Secondly, while the proportion of widows has increased since the turn of the century, the proportion of widowers has declined. This change needs to be set in the context of improvements to life expectancy and falls in death rates which have been greater for females than males since 1901, thus increasing the likelihood that married women will survive their husbands.

POPULATION AGED 15 AND OVER: MARITAL STATUS BY SEX (a), AUSTRALIA

(a) Not-stated for 1921, 1933, 1947 and 1954 were: 1921, males 0.5 per cent, females 0.3 per cent; 1933, males 0.6 per cent, females 0.3 per cent; 1947, males 0.4 per cent, females 0.4 per cent; 1954, males 0.3 per cent, females 0.2 per cent. Proportions may not total 100 per cent due to rounding. Figures for 'Married but Permanently Separated' included with 'Married' until 1947 Census and 'Divorced' unavailable prior to 1901 Census.

Birthplace

After the arrival of European settlers and the numerical decline of the Aboriginal population, the British rapidly became the most populous birthplace group in Australia. However, by the 1860s, natural increase had become the major component in population growth and by the 1870s, the majority of the population were born in Australia. Thereafter, the overseas-born declined as a proportion of the total population until after World War II, when there was a reversal of the trend. In 1881, the overseas-born comprised 36.8 per cent of the population; by 1947 this had fallen to 9.8 per cent while numbers declined from over 1,000,000 at the 1891 census, following the immigration boom of the 1880s, to 744,200. By 1986, however, the overseas-born had increased to 20.8 per cent of the total population, numbering 3,247,381.

(a) Included in 'Other', except for U.K. and Eire. (b) Included in 'Other Europe'. Percentage distribution may not equal totals due to rounding error.

The composition of the overseas-born population between 1788 and 1947 remained predominantly British, although the gold rush in the 1850s encouraged the proliferation of a wider range of nationalities. For example, in Victoria non-British subjects increased from 1,500 to 46,000 between the 1851 and 1861 censuses and one man in five was estimated to be Chinese at some of the gold diggings.

This diversification was short-lived. Many of the miners were transients who subsequently left for the New Zealand goldfields, while restrictive immigration practices imposed during the second half of the 19th century, curtailed Chinese and other non-European migration. By the 1891 census, following high levels of immigration during the 1880s, 81.7 per cent of

the overseas-born were from the United Kingdom and Ireland, comprising 25.7 per cent of the Australian population at the time, while the other larger birthplace groups—Germany and China—comprised only 1.4 per cent and 1.1 per cent of the Australian population respectively.

With the adoption of the 'White Australia' policy after Federation, and emphasis on United Kingdom migration throughout the first half of this century, the extent of representation of other overseas birthplace groups in the Australian population diminished further. By 1947, 97.9 per cent of the Australian population were either born in Australia or the United Kingdom, Ireland or New Zealand. The largest non-British overseas-born group, the Italians, comprised only 0.4 per cent of the population (33,600), while the number of overseas-born Chinese had fallen from 36,000 in 1891 to 6,400 by 1947.

Since 1947, not only has the decline of the overseas-born population been reversed, significant changes have taken place in the composition of that group. The progressive removal of immigration restrictions based on country of origin, race or colour between 1949 and 1973, together with the extension of assisted migration schemes to some non-British groups and refugees, have ensured a greater diversity of ethnic origin among the Australian population (*see also section on Overseas Migration*). The relative size of overseas-born groups from the United Kingdom, Eire and New Zealand combined, increased only slightly as a proportion of the total population between 1947 and 1981, from 7.7 per cent to 9.0 per cent. However, overseas-born persons from other countries increased from 2.1 per cent to 11.6 per cent during the same period. Overseas birthplace groups comprising 0.1 per cent or more of the total population—apart from the United Kingdom, Eire and New Zealand—increased in number from 4 in 1947 to 14 by 1954 and 26 by 1981.

The largest overseas-born group at the present time remains those born in the United Kingdom and Ireland, having more than doubled in number from 541,300 to 1,127,200 between 1947 and 1986. By comparison, the second largest overseas-born group, Italians, comprised only 1.7 per cent of the Australian population in 1986 (261,900). Eight of the first nine large overseas-born groups are European, the exception being New Zealand which comprised 1.4 per cent of the population and ranked third after Italy in 1986. Although Europe remains the region of origin of the majority of the overseas-born population, European-born persons declined as a proportion of the total Australian population between 1971 and 1986, while persons born in other regions increased their share. Between 1971 and 1986, the European-born population increased by only 39,000 compared with an increase of 369,000 in the Asian-born group.

The proportion of the Australian population born in Asia has increased continually from 0.3 per cent in 1947 to 3.4 per cent in 1986. As recently as 1966, however, only two Asian birthplace groups had populations amounting to more than 0.1 per cent of the Australian population, namely China and India. By 1981 this number had increased to nine. Sources of the largest Asian-born populations in 1986 were Vietnam (83,040), Lebanon (56,340), India (47,820) and Malaysia (47,800), comprising 0.5, 0.4, 0.3 and 0.3 per cent of the Australian population respectively.

In 1986, 77.6 per cent of the population was born in Australia. Of these, 74.9 per cent reported Australia as the birthplace of both their parents. This implies that 58.1 per cent of the total population of Australia are at least second generation Australians. A further 13.7 per cent of the Australian-born population (10.6 per cent of the total population) had one parent born in Australia. Conversely, 41.9 per cent of the total population were either born overseas or had at least one parent born overseas.

BIRTHPLACE OF PARENTS OF AUSTRALIAN BORN PERSONS, AUSTRALIA, CENSUS 1986

<i>Birthplace of parents</i>	<i>Numbers</i>	<i>Percentage</i>
Both parents born in Australia	9,070,739	74.9
1 parent born in Australia, 1 born overseas or not stated	1,657,548	13.7
Other	1,382,169	11.4
Total	12,110,456	100.0

Citizenship

The grant of citizenship is controlled by the *Australian Citizenship Act 1948*. Prior to 26 January 1949, aliens who were naturalised became British subjects and, with the introduction of the Act, all such persons automatically became Australian citizens.

Citizenship may be acquired by birth in Australia provided that at the time of birth one of the parents is an Australian citizen or legal resident of Australia, by birth abroad to an Australian parent, or by grant of citizenship to a person resident in Australia under conditions prescribed in the Act. All persons are now eligible for the grant of Australian citizenship provided that they have resided in Australia for at least two years, are of good character, have an adequate knowledge of English and of the responsibilities and privileges of citizenship, and intend to reside permanently in Australia.

At the 1981 Census, 88.7 per cent of the population were Australian citizens, with 11.9 per cent of these being born overseas.

COUNTRY OF CITIZENSHIP, AUSTRALIA, 1981

Country	Persons	Percentage
Australia—		
Born in Australia	11,393,861	78.2
Born overseas	1,537,212	10.5
Other Commonwealth countries	961,155	6.6
Non Commonwealth countries	452,499	3.1
Stateless and Not-stated	231,603	1.6
Total	14,576,330	100.0

Religion

Details on religious affiliation have been collected in all Australian censuses, however since the 1933 Census, it has been clearly stated on the census form that the question on religion is not obligatory. This clarification resulted in a large increase in the numbers of people responding 'no religion' or simply not answering the question, with these responses combined increasing from 2.4 per cent in 1921 to 13.2 per cent in 1933. By 1981, 22.3 per cent of the population described themselves as either having 'no religion' or did not answer the question.

Census data show that the Australian population is predominantly Christian with similar proportions associating themselves with the two major groups, the Church of England and the Catholic Church (26.1 per cent and 26.0 per cent respectively at the 1981 Census).

MAJOR RELIGIOUS GROUPS, AUSTRALIA, SELECTED CENSUS DATES (per cent)

Year	Church of England	Catholic	Other Christian	Total Christian	Non- Christian	Not stated or No Religion	Total
1861	(a) 43.9	22.3	27.4	93.6		6.4	100.0
1901	40.3	23.0	34.2	97.5	1.4	1.0	100.0
1921	43.7	21.6	31.7	96.9	0.7	2.4	100.0
1933	38.7	19.6	28.1	86.4	0.4	13.2	100.0
1947	39.0	20.9	28.1	88.0	0.5	11.5	100.0
1961	34.9	24.9	28.4	88.3	0.7	11.1	100.0
1971	31.0	27.0	28.2	86.2	0.8	13.1	100.0
1981	26.1	26.0	24.3	76.4	1.4	22.3	100.0

(a) Includes Protestant undefined.

The remainder of the Christian population, amounting to 24 per cent of the total population at the 1981 Census, is dispersed between several other groups, with only four denominations consisting of more than 2.0 per cent of the population; the Uniting Church (4.9 per cent), Presbyterian (4.4 per cent), Methodist (3.4 per cent) and Orthodox (2.9 per cent).

There has been a slight increase in the proportion of persons of non-Christian religions since 1947, from 0.5 per cent to 1.4 per cent in 1981. At the 1981 Census, Muslims comprised 38.9 per cent of the non-Christian response, Hebrews 31.4 per cent and Buddhists 17.8 per cent.

Households

The incidence of household formation in Australia has exceeded population growth rates since 1911, with the average number of persons per household declining from 4.5 in 1911 to 2.9 in 1986. Major declines occurred throughout the period in the numbers and proportion of households with five or more persons. Much of the decline in the number of persons per household this century can be attributed to reductions in completed family size. There has been considerable growth in one and two-person households for most of this period, these households almost doubling as a proportion of all households from 24.1 per cent in 1911 to 47.2 per cent by 1981.

POPULATION IN PRIVATE HOUSEHOLDS, AUSTRALIA

The incidence of household formation and household size has been affected by social and economic factors, such as the availability of mortgage finance schemes repayable in instalments—which were introduced shortly before the 1920s—as well as demographic changes.

HOUSEHOLD SIZE: NUMBER OF PERSONS IN HOUSEHOLD, AUSTRALIA

During the 1960s and 1970s, for example, there was an increase in the proportion of the population aged 15–29 years—prime years for household formation as young adults leave the parental home—from 20.6 per cent in 1961 to 25.6 per cent by 1976. This increase resulted both from high birth rates during the post World War II 'baby boom' years after 1947, and high rates of immigration of those aged 20–29 years during the 1960s. The rapid rise in numbers of 15–29 year olds coincided with a period of economic growth and high rates of employment until the 1970s, providing a favourable environment for household formation.

Increases in the number of households have also been affected by a complex combination of factors at older ages. The proportion of the population aged 65 years and over has increased throughout most of the last century, as a result of increases to life expectancy, while both completed family size and age at completion have generally declined. Thus, older families are likely to experience several years of 'empty nesting', that is time lived in the household without dependants after children leave home. There has been a tendency for increasing numbers of older couples and older persons who are widowed, particularly females, to remain as separate households to a later age—with long-term cumulative affects on the total number of households.

Only a small proportion of households include more than one family, some 3 per cent at the 1981 Census. Improved data on family relationships are available from the 1986 Census, where information coded on family relationships includes members of the family temporarily absent from the household on Census night.

Some information on the structure of Australian families is available from the *1982 Family Survey* (4408.0). This survey indicated that almost 90.0 per cent of the population lived with other family members, while the remaining individuals were most likely to be living alone (67.5 per cent) rather than with persons to whom they were unrelated (32.5 per cent). Among family groups, 87.7 per cent were married couple families, 10.7 per cent were one parent families, while the rest comprised persons related other than as spouse or parent/offspring. Some 5.5 per cent of married couples and one parent families had relatives other than offspring living with them.

An estimated 66.1 per cent of all families had offspring living in the household, and among families with offspring present, 80.7 per cent had at least one dependent child present (i.e. aged less than 15 years, or 15–20 if in full-time study).

Overall 33.7 per cent of families with offspring had only one offspring present in the household, while 72.7 per cent had either one or two. The average number of offspring present was 2.1 per family, 1.6 dependent and 0.5 non-dependent. One parent families, however, were smaller than married couple families, with 43.0 per cent of one parent families with dependent children consisting of only one child compared with 22.7 per cent of married couple families with dependent children.

FAMILY TYPE AND COMPOSITION, AUSTRALIA, 1982 (a)
(*000)

Married couples (b) (c)—	
Without offspring—	1,317.0
Living alone	1,278.9
With other relatives present	38.1
With offspring—	2,254.7
Non-dependent offspring only	343.0
Non-dependent offspring and other relatives	19.2
At least one dependent child (d)	1,826.6
At least one dependent child and other relatives (d)	66.0
One parent family (b)—	
With offspring—	436.6
Non-dependent offspring only	151.1
Non-dependent offspring and other relatives	6.3
At least one dependent child (d)	262.1
At least one dependent child and other relatives (d)	17.1
Other family groups	
Persons related other than as spouse or parent/offspring	62.1
All family groups	4,070.5

(a) Figures may not total due to rounding. (b) Previously married persons without partners or offspring present or not living with other relatives are not classified as 'Families' and not included in this table. (c) 'Married Couples' includes de-facto couples. (d) Includes families with dependent children only and families with both dependent and non-dependent offspring present. The term 'dependent' is defined as a child aged less than 15 years or 15–20 years if in full-time study.

VITAL STATISTICS

Registration of vital events, i.e. births, deaths and marriages, has been compulsory throughout Australia since 1856. The total number of these registrations is available for each year since the 1860s and more detailed information since the 1910s. The number of divorces has been published since 1891, but other details have been published on a consistent basis only since the 1950s.

Births

Current fertility levels in Australia are lower than at any time since European settlement. Crude birth rates declined from 42.6 per thousand population in 1860 to 27.2 in 1901 and to 15.2 in 1986. Australia's current fertility rates, however are higher than several other industrialised countries in Northern Europe and Japan.

CRUDE BIRTH RATES AND TOTAL FERTILITY RATES, LOW FERTILITY COUNTRIES

Country	Crude birth rate		Total fertility rate (a)	
	1970	1980s	1970	1980s
Australia	20.6	15.2 (1986)	2.86	1.87 (1986)

Sources: United Nations. *Demographic Yearbook 1985*. New York, except total fertility rates 1980s, France, Federal Republic of Germany, Switzerland, U.S.A. in Muñoz-Perez, F. "Changements récents de la fécondité en Europe occidentale et nouveaux traits de la formation des familles", *Population*. Vol. 41, 3, 1986.

Despite an overall fertility decline, the number of births has shown an increasing trend. This has been caused by a continued increase in the number of women of reproductive ages. However, the rate of increase has varied, with annual average births rising from over 50,000 to 100,000 in the 25 year period between 1861-65 and 1886-90, but taking more than the next 50 years to reach 150,000 by 1944. Birth numbers then increased very rapidly in the immediate post-war period to reach over 200,000 a year by 1952 and exceeded 250,000 per year between 1969 and 1972, reaching a peak of 276,400 in 1971. The sharp rise in births during the late 1960s and early 1970s is due to the 'echo-effect' as children of the post-World War II 'baby-boom' moved into their childbearing years and started their own families. Between 1981 and 1985 the number of births averaged 240,000 annually.

Although fertility decline is evident since the 1860s, this trend has not been continuous, and at times fertility has increased. Major declines continued well into the depression years of the 1930s, but then fertility recovered in the following years to 1961. Despite temporary halts between 1965 and 1971, fertility has generally declined until the present time.

A number of changes occurred from the mid-1930s which contributed to increasing fertility levels until recent times. The proportion of women marrying began to rise, while the proportion remaining childless fell. In the late 1940s, the increasing number of births from these trends coincided with births that had been postponed during World War II. However, high levels of fertility were sustained during the 1950s as the timing of births changed. Women began marrying earlier and having their children at a younger age, which is reflected in the rapid rise of the age-specific birth rate for the 20-24 year age group. In addition birth rates for women up to age 40 remained higher than they had during the early 1930s depression years, resulting in increasing levels of total fertility.

(a) Excludes full-blood Aboriginals prior to 1966. (b) Includes births to mothers aged less than 15. (c) Includes births to mothers aged 50 and over. (d) Rates are adjusted for late registrations of New South Wales births in 1984.

TOTAL FERTILITY RATES, AUSTRALIA (a)

(a) Excludes full-blood Aboriginal population before 1966.

From the late 1950s and the early 1960s, fertility levels began to decline. In 1961, oral contraception became widely available in Australia contributing to, or accelerating, fertility decline, which was most noticeable among the older age-groups as women began completing child-bearing earlier. Changes to child-bearing patterns also occurred at younger ages. The duration between marriage and first nuptial confinement began to increase, and by 1965 the proportion of women who were pregnant at the time of marriage began to decrease.

MARRIED FEMALES UNDER 45 YEARS OF AGE AT TIME OF MARRIAGE: YEAR MARRIED AND TIMING OF FIRST NUPTIAL CONFINEMENT

Year of marriage	Percentage of married females under 45 years of age at time of marriage							Number of brides aged under 45 years

1985	9.2	15.4	—	—	—	—	—	109,377

(a) Premaritally pregnant comprises wives who delivered their first child within marriage duration of 0-7 completed months. (b) Include premarital pregnancies.

In the 1970s, fertility declines became obvious across all age-groups, falling rapidly between 1971 and 1980, and marginally since then. This decline has been attributed to demographic, social, economic and attitudinal changes of the 1970s, which individually or collectively influenced fertility behaviour during this period. Between 1971 and 1986, the total fertility rate for all ages declined by 35 per cent. The largest declines in age-specific

fertility rates occurred to younger women aged 15-29 years, in particular the 20-24 age group. Compared with women in the 1960s, women in the 1980s are more likely to defer and restrict child-bearing to the middle range of their reproductive years. In 1961-65, 81.0 per cent of births occurred to women aged 20-34. By 1986, the corresponding figure was 86.0 per cent. Women in the 25-29 age group maintained the highest fertility rates.

Concurrent with the downward movement that has occurred in the levels of fertility, the family building patterns of couples has changed. An increasing proportion of total births has now been occurring outside marriage, and for those occurring within marriage, concentration has been on the first and second order births.

Confinements resulting in ex-nuptial births have increased continually as a proportion of total confinements from the 1950s to the present time increasing from 4.5 per cent in 1956-60 to 16.9 per cent in 1986. The median age of ex-nuptial mothers has been lower than that at first nuptial confinement and it seems likely that ex-nuptial births are predominantly first order births.

(a) Excludes full-blood Aboriginals prior to 1966. (b) These figures have been affected by late registration in New South Wales.

Since the 1950s there has been a decline in the proportion of females having three or more children in their marriage. Between 1956 and 1960, 58.7 per cent of nuptial confinements resulted in the first or second child of a marriage. In 1986, 75.2 per cent of confinements resulted in first or second children. The proportion of nuptial confinements that produced a fourth or higher order birth declined from 21.8 per cent between 1956 and 1960 to 7.8 per cent in 1986.

Deaths

Numbers of deaths a year in Australia have risen from 23,400 in 1860 to 118,800 in 1985. However, relative to the growth of the population throughout that period, crude death rates per 1,000 population have fallen—from 20.9 in 1860 to 10.7 in 1911 and to 7.4 in 1985. With the exception of the years during World War II, declines in crude death rates have been virtually continuous. In comparison with other countries, Australia ranks amongst those with the lowest mortality levels and the highest expectations of life.

BIRTHS AND DEATHS(a), AUSTRALIA

(a) Excludes full-blooded Aboriginals before 1966.

RATES OF BIRTHS AND DEATHS(a), AUSTRALIA, 1860-1985(b)

(a) Per 1000 mean population. Excludes full-blooded Aboriginals before 1966.

(b) There is a break in continuity due to revision in the methods used to calculate population estimates between 1961 and 1962, and between 1971 and 1972.

(a) Total United Kingdom.

The crude death rate, as a measure of mortality, is distorted by changes in the age structure of the population over time. The fall in death rates is considerably greater if the population is standardised in terms of age structure. Using 1911 as a base year, the age adjusted death rate fell from 11.9 to 5.0 per thousand for males and from 9.5 to 2.8 per thousand for females by 1985.

(a) Excludes full-blood Aboriginal population prior to 1966. (b) Adjusted for late registrations in New South Wales. (c) Life tables up to 1975-77 are official life tables compiled by the Australian Government Actuary. The 1985 life table was compiled by the Australian Bureau of Statistics.

The decline in death rates has been brought about primarily through improvements to community health care and advances in medical science and technology. A series of comprehensive health Acts were passed towards the end of the 19th century and efforts were made to improve infant nutrition. These advances were followed by improvements to hospital care and antiseptic surgery, the discovery of antibiotics and the development of immunisation programs. As a result, many of the infectious and diarrhoeal diseases, maternal mortality, pneumonia and tuberculosis were brought under control by the 1950s with consequent reductions in mortality rates from these causes.

In Australia, as in most other countries, females have lower death rates than males. In 1985 the female death rate in many age groups was about half that of males. The relative difference between death rates for males and females was greatest in the age group 15 to 24 years where in 1985 the female rate was about one-third that of males. The overall effect of these differences in death rates has been to increase the proportion of females in the older age groups of the population.

(a) Excludes full-blood Aboriginals prior to 1966. (b) Rates are not available as population estimates for males in these age groups exclusive of defence personnel were not compiled for the period September 1939 to June 1947. (c) Adjusted for late registrations in New South Wales.

Concurrent with the decline in death rates has been a rise in life expectancy at birth, increasing for males from 47.2 years to 71.2 years between the periods 1881-1890 and 1980-1982, and correspondingly for females from 50.8 years to 78.3 years. Female life expectancy at birth has exceeded that of males throughout the period, with the difference increasing until 1980-1982. Contributing to the increase in life expectancy at birth is the reduction in infant mortality, falling from rates of 115.8 per thousand in 1881 to 10.0 per thousand by 1985. These changes reflect a very significant improvement in chances of survival from birth to age 1 year. The considerable difference between life expectancy at birth and at age 1 year which existed in the 1880s has disappeared and life expectancy at birth now exceeds life expectancy at age 1 year.

(a) Excludes full-blood Aboriginals until 1966. (b) Adjusted for late registrations in New South Wales.

Changes in levels of mortality and age-specific death rates reflect trends in the incidence of specific causes of death. The three most prevalent causes of death for both sexes at the present time are ischaemic heart disease, cancer and cerebrovascular disease or stroke. In recent years there have been decreases in the incidence of most of the major causes of death with the exception of cancer, with age-standardised death rates falling by half or more for some classes of disease between 1966 and 1986.

(a) Per 100,000 persons, standardised to age distribution for persons, 1981.

Cause of death is age-related, with different causes assuming greater or lesser significance in persons of different age groups. The most common causes of death during the first year of life are the culmination of conditions originating in the perinatal period. These include prematurity, birth injury and respiratory conditions present from birth. Thereafter, motor vehicle accidents are the most common cause of death for males aged under 45 and for females aged under 25. In the 15-24 age group, death rates from both motor vehicle accidents and suicide are far higher for males than for females, with more than twice as many deaths among males than females in this age group in 1985.

For females aged 25 years and over, malignant neoplasms, particularly cancer of the breast, become the major cause of death and remain so until the age of 65 when both heart disease and stroke surpass cancer as the main cause. For males aged 45 years and over, heart disease and circulatory disease become the main cause of death and the rate continues to increase thereafter.

Marriages

Numbers of marriages recorded in Australia have risen from 10,000 in 1861 to annual averages of nearly 25,000 at the end of the 19th century, almost 65,000 between 1936 and 1940, and reaching 115,000 by 1985. Exceptions to the general increase in numbers occurred during the economic depressions of the 1890s and 1930s and, more recently, during the 1970s. Both World Wars this century created major fluctuations to numbers marrying, distorting for a time the overall trend.

1986	76,674	66.7	38,239	33.3	114,913	7.2

(a) There is a break in the continuity due to revision of methods used to calculate population estimates between 1961 and 1962, and between 1971 and 1972.

Throughout this century there have been two periods of rising marriage rates, firstly from the mid-1930s until just after World War II, and secondly from the early 1960s to the early 1970s. During the first of these periods, the crude marriage rate rose from annual averages of 7.2 per 1,000 population during 1931-35 to 9.7 over the next 15 years, reaching the highest rate on record in 1942, at 12.0 per 1,000 population, when 86,000 marriages were registered. The second period of rising marriage rates occurred during the 1960s and early 1970s, following stabilisation of marriage numbers during the 1950s, when these averaged 73,500 annually. The number of marriages rose to a peak of 117,600 in 1971 before falling back to 104,000 by 1975.

In contrast with the beginning of the 20th century, three changes in marriage patterns had taken place by the early 1970s. Firstly, a far higher proportion of people were marrying; secondly, the age range across which marriage took place had narrowed with a definite

preference for marriage at a younger age; thirdly, differences between the sexes relating to age at marriage had been reduced, with marriage patterns for males conforming more closely to those of females. Changes to proportions marrying are covered in the previous section on marital status of the population.

(a) Excludes full-blood Aboriginals before 1966.

The shift to younger marriage was already evident from declines in median age at first marriage prior to the 1930s, but postponements of marriage during the economic depression subsequently increased the median age when these delayed marriages eventuated in the second half of the 1930s. Between the 1936-40 and the 1971-75 periods, however, median age at first marriage declined from 26.7 years to 23.3 years for males and from 23.7 years to 21.0 years for females. Until the early 1960s, the difference between median age at marriage of males and females remained around 3.0 years. However during the 1960s this gap became smaller, falling to 2.3 years by 1971 as the age at first marriage for males became younger. Between 1956-60 and 1966-70, while the ratio of first marriages for females aged 20-24 remained virtually static, the ratio for males of the same age increased from 484.8 to 553.8 per thousand.

(a) Per 1,000 mid-year population of males and females of each age. There is a break in the continuity due to the revision of methods used to calculate population estimates between 1961 and 1962, and between 1971 and 1972. (b) Excludes full-blood Aboriginals prior to 1966. (c) Ratios for each age-group are calculated by summing the ratios for single years. (d) The sum of all single year ratios. (e) These ratios have been affected by late registrations of births, deaths and marriages in New South Wales.

Since the early 1970s, new marriage patterns have emerged. Firstly, while total numbers of persons marrying recovered during 1981-85 to an annual average of 114,000 (higher than the previous peak of 111,800 during 1971-75), the numbers of marriages in which neither party has been previously married has fallen during that time, from annual averages of 93,700 during 1971-75 to 77,000 between 1981-85. Secondly the median age at first marriage has risen during the last decade from 23.3 years to 24.9 years for males, and from 21.2 years to 22.7 years for females. However, the age differential between the sexes at first marriage has remained almost constant at 2.3 years.

The decline in first marriage ratios and increase in the median age at first marriage over the last decade may reflect to some extent the tendency of some couples to live together before getting married. Although there is no reliable time series data on this group, the Family Formation Survey conducted in 1986 estimated that 68,600 females aged 20-29 years were living in a de facto marriage relationship. This represented 5.2 per cent of all females in this age group.

1971-75	17,348	1986	39,417

(a) Includes small numbers of nullities between 1891-1950.

For most of this century there has been a slow but steady rise in the numbers of divorces granted each year, increasing from annual averages of 400 between 1901-10 to 9,120 between 1961-70. However, the most important factor involved in rising divorce rates in recent times has been the introduction of the *Family Law Act 1975* which came into operation on 5 January 1976. This legislation provides for a single ground for divorce, namely irretrievable breakdown of marriage, which is established by a minimum one-year separation of the husband and wife.

Removal of the need to prove fault, together with reduction of the separation period from five years to one year, has provided easier and faster access to divorce for either party. After the introduction of the Family Law Act, the number of divorces per year rose from annual averages of 17,350 to 45,220 between 1971-75 and 1976-80, while the median duration of marriage of divorcing couples decreased from 12.5 years in 1971 to 10.2 years in 1981, before increasing slightly to 10.6 years in 1986.

(a) Discontinuity in the series due to the *Family Law Act 1975* which came into operation on 5 January 1976.

There has been an increasing tendency for divorce to occur in the early years of marriage and at an earlier age. The proportion of divorces taking place within the first five years of marriage more than doubled from 9.9 per cent in 1975 to 20.7 per cent in 1980, and continues to rise. Similarly, while increases in the divorce rates have occurred in all age categories since the introduction of the Family Law Act, the largest increases have occurred among couples in the younger age-groups. In 1981 the highest divorce rates for both males and females occurred in the 25-29 year age group.

MARRIAGES AND DIVORCES, AUSTRALIA

1981	18.0	22.0	16.9	14.7	11.8	8.9	6.2	4.1	1.8	11.9

There has been a recent increase in the proportion of divorces which do not involve children, from 32.4 per cent during 1971-75 to 39.4 per cent in 1985. Where divorce involves children, the average number of children per divorce has fallen from 2.1 to 1.9 in the period between 1971-75 and 1981-85, although the total number of children affected by divorce has risen as the overall numbers of divorces has increased.

DIVORCES: PERCENTAGE DISTRIBUTION OF THE NUMBER OF CHILDREN OF THE MARRIAGE, AUSTRALIA

(a) Divorces involving one or more children.

There is some evidence to suggest that the incidence of divorce is now decreasing. The number of divorces granted has fallen continually since 1982.

Remarriages

There has been a significant increase throughout this century in both the numbers and proportions of marriages in which one or both parties have been previously married. The average annual number of such marriages has increased from 4,368 in 1911-20 to 38,239 in 1986, increasing as a proportion of total marriage from 10.6 per cent to 33.3 per cent during this time.

1981-85(b)	12,125	32.7	22,399	60.5	2,511	6.8	37,035
1986(b)	12,823	33.5	22,918	59.9	2,498	6.5	38,239

(a) One or both partners widowed. (b) The statistics for 1984, 1985 and 1986 were affected by late registrations in New South Wales.

This change has been brought about by the almost continuous growth in the numbers of marriages in which one or both parties were divorced at the time of remarriage. Such marriages have increased from annual averages of 621 between 1911-20 to 35,741 in 1986 and, as a proportion of marriages involving remarriage, from 14.2 per cent to 93.5 per cent over that time.

While the move to predominance of divorced persons among those remarrying has been ongoing throughout most of this century, increases were particularly noticeable at the time of World War II and following the operation of the Family Law Act in 1976. Sharp rises in the number of divorces took place in both these periods, followed by increases to remarriage rates for both sexes.

1981	113,905	3,727	21,870	25,597	6.1	96.9	30.5

(a) Per thousand widowed or divorced persons. (b) Per thousand married persons.

Compared with the rapid rise in numbers of divorced persons remarrying throughout this century, the number of widowed persons remarrying has increased very slowly.

MIGRATION

Statistics of overseas arrivals and departures are compiled from incoming and outgoing passenger cards which are collected from all travellers under the *Migration Act 1958*. Earlier statistics were obtained from Shipping and Plane manifests required under various Acts.

Since 1924, overseas travellers have been classified into two principal categories which distinguish short-term movements (of less than 12 months duration) from long-term movements (of 12 months duration or longer, including permanent movements). Revised questions for travellers were introduced in 1959 and again in 1974. The 1959 revision enabled the distinction of permanent from other long-term movements and also the identification of former settlers departing permanently. The 1974 revisions improved the layout of the passenger card without changing the classification.

Migration to Australia

Migration to Australia is presently regulated by the *Migration Act 1958* which came into force on 1 June 1959. Any person entering Australia after the introduction of the Act without having been granted an entry permit or who is not within an exempted class is a prohibited non-citizen. Exempted persons include New Zealand citizens, diplomatic and consular representatives of other countries, and seamen and air crew who enter Australian ports while on leave.

Until recently, net gains provided a satisfactory measure of the population gain from international migration (i.e., the excess of total arrivals over total departures). In recent years, however, because of the large increase in short term movements (over 6 million in 1986), distortions arising from seasonality of these movements have become very large. For the purpose of estimating the population of Australia and the States and Territories, therefore, the migration component of population growth has been measured since 1 July 1971 by reference to permanent and long-term movements only.

Net migration is estimated to have directly contributed 34.0 per cent of the total population increase between European settlement in 1788 and 1980. The first boost to free settlement came with the introduction of assisted migration schemes during the 1830s, with nearly half of the 2.5 million settlers arriving up to 1939 receiving assisted passage. Over 95.0 per cent of those assisted were British.

In the period since World War II, British migrants have remained the most numerous group of settlers. However, the group has declined in absolute numbers since the 1970s and as a proportion of total settler arrivals since the 1960s, from 46 to 48 per cent in the 1950s and 1960s to 25.2 per cent in 1981-85.

(a) Permanent arrivals only. (b) The statistics for some listed countries do not relate to the whole period 1961 to 1985 i.e. the statistics for Vietnam relate to the period 1974-85; Turkey, 1966-85; Philippines, 1971-85; Malaysia, 1971-85; Hong Kong, 1976-85; Kampuchea, 1974-85. (c) The statistics for this country are not separately available but are included in the category 'Other'.

In contrast, source countries of migrants have diversified and the number of non-British migrants has increased. Two factors have contributed to this shift. Firstly, entry conditions to Australia were eased after World War II initially for European refugees from Displaced Persons Camps then, subsequently, restrictions relating to other racial groups were removed. Secondly, assisted passage was extended to a wider range of migrants. Originally this included Central and Eastern European refugees after World War II, then German and Dutch settlers in the 1950s and 1960s, Southern European and Middle-East groups from the 1960s and, more recently, Indo-Chinese refugees. Between 1946 and 1980 some 53.7 per cent of settlers were assisted, reaching an average of 66.8 per cent during the boom migration years of 1966-70. In recent times, however, assisted passages have been phased out with the exception of refugees.

Annual totals—					
1981	29,960	25.2	88,780	74.8	118,730
1982	20,200	18.8	86,970	81.2	107,170
1983	16,370	15.5	62,020	84.5	78,390

(a) From 1946-50 to 1983 figures for assisted settlers include assisted refugee arrivals. After 1981, applications for assisted passage were limited to refugees and special applicants, however figures for 1982 and 1983 include persons whose applications for assistance were processed under the previous scheme. The 1983 total for assisted settlers was provided by the Department of Immigration and Ethnic Affairs.

Statistics for birthplace of migrants are only available since 1959. However, some indication of migration by the largest non-British groups since World War II can be obtained by using data on nationality and birthplace of migrants. Between 1948 and 1985 approximately 8.7 per cent of all migrants were Italian, 5.1 per cent were Greek, 4.4 per cent were Yugoslavs, 3.8 per cent were Dutch, 3.4 per cent were Germans and 2.4 per cent were Poles.

(a) 'Permanent arrivals' includes permanent and long-term movement exceeding 12 months. (b) Includes New Zealand and all British Commonwealth countries during the respective periods.

The contribution of various groups has changed over time, with northern Europe declining as a major source of migrants (apart from the British) by the 1960s, while southern European countries provided the greater part of non-English speaking migrants throughout the 1960s. From the mid-1960s to the mid-1970s, migrants from the Middle-East and India increased in numbers. More recently, since 1975, there has been an upturn in migrants from South-East Asia and Hong Kong, and particularly refugees from Indo-China. Between 1981 and 1985, Vietnamese-born arrivals accounted for 10.3 per cent of Australia's settler intake.

Since 1978-79, family immigration has increased in importance, with migration of family members now amounting to over 50 per cent of settler arrivals. Another recent trend has been the increase in non-visaed migrants in Australia. These are primarily New Zealand citizens migrating under the Trans-Tasman Travel Arrangement under which Australian and New Zealander citizens may enter each country without the need to obtain visas or entry permits. Other non-visaed migrants include children born to Australian citizens overseas, persons who have acquired Australian citizenship overseas and residents of Norfolk Island (an Australian Territory). New Zealand migrants increased numerically from 17,500 to 48,600 between 1971-75 and 1981-85 and as a proportion of total migrants from 3.2 per cent to 10.6 per cent between those periods.

The age composition of settlers has been younger than that of Australia's population for some time. The median age of settlers arriving between 1971 and 1984 was 24.0 years compared with 29.7 years for the population as a whole at the time of the 1981 Census and the age structure of settlers reflects the predominance of young families arriving in Australia. Persons aged 65 years and over represented 3.6 per cent of migrants arriving between 1971 and 1985, which contrasts with the share of these people in Australia's population of 9.8 per cent in 1981.

1981-85	12.0	18.3	19.2	38.0	8.6	4.0	91,882

Despite the youthfulness of the settlers, their median age has been rising. In 1971 it was 23.1 years and in 1984 it was 26.0 years. This rise has been particularly marked since 1981, when the numbers of migrants under the 'family reunion' category began to increase. At the younger ages, declines have taken place since the mid-1970s in the proportion of settlers in the 15-24 year age group while there has been an increase in the proportion of settlers aged 45 and over.

The sex ratio of settlers has declined almost continually between 1948-50 and 1976-80, with the exception of the 1961-65 period. The sex ratio tends to be high in years of large intake, and falls as intake declines. Males have constantly exceeded females in the 25-44 year age group, although the sex ratio has fallen closer to equality since the mid-1970s. Traditionally, the sex ratio of the overseas born has been higher than the Australian born population.

Refugees

Since 1945, Australia has accepted more than 420,000 refugees or displaced persons, including 170,000 from Europe who were displaced by World War II and its aftermath.

Australia presently accepts refugees from about 40 countries. The largest element in Australia's current refugee intake is the Indo-Chinese program. In 1984, 8,537 Indo-Chinese refugees were resettled in Australia.

(a) Includes arrivals under the Special Humanitarian Program instituted late in 1981.

Australia is one of 97 countries which have become party to an international convention and protocol on the status of refugees and, in so doing, have taken on certain international legal obligations to assist refugees. The final determination of a refugee's status and the decision to accept those refugees for resettlement in Australia rests with the Australian

Government. Australia is also a member of the Executive Committee of the United Nations High Commission for Refugees (UNHCR). Australia's response to refugee situations is twofold. Through aid programs directed principally through UNHCR, refugees are offered protection and assistance in countries of first refuge. Those refugees for whom other durable solutions are not feasible may be offered resettlement (in Australia) if they have relatives in Australia, other close ties with Australia or the potential for successful settlement in their own right. Such refugees must also be presented to Australia by the UNHCR as being registered or otherwise eligible for resettlement.

Permanent departures

An important influence on the level of population growth is the level of population loss due to outmigration. Between 1971 and 1985, total permanent departures numbered 421,135 persons or an average of 28,076 per year, a level which is 30.6 per cent of the total permanent arrivals in Australia in this period. In other words, for almost every three settlers who arrived during the period, one person has left Australia. The number of departures has declined however since the early 1970s. During the five years between 1981 and 1985, total permanent departures were at a level of 23.8 per cent of total permanent arrivals.

1985	10,020	8,600	18,620	82,000	0.227

Of the two categories of permanent departures, that is 'former settlers' and 'other residents', it has been under the first category that there has been the greatest outflow of persons. Between 1971 and 1984, 'former settlers' represented 63.6 per cent of all permanent departures. The departure of 'other residents' fluctuated between 9,000 and 13,000 persons from year to year throughout the period. The fall in the total number of departures, noted above, is largely attributable to the decline in the number of 'former settlers' departing. There are two major reasons for this decline, the first relates to the decline in the number of settler arrivals in the early 1970s and the second to the shift in origin of immigrants towards refugees for whom there are indications that they are less likely than other settlers to return to their own country.

Internal migration

Information on internal migration has been available from the censuses since 1971 and from the annual Internal Migration Survey since 1970. A good indicator of internal movement over the long term is the duration of stay at a person's usual residence, although this indicator is age-selective and, for the overseas-born, dependent on the year of arrival in Australia. According to the Internal Migration Survey, at 31 May 1986, 74 per cent of persons aged 15 and over had lived at their current usual residence for less than 15 years—that is they had moved at least once during the past 15 years.

Recent Internal Migration Surveys show that about 16 per cent of all persons change their residence within a twelve month period. Of those who change their residence, about 50 per cent remain within the same capital city and another 40 per cent within the same State or Territory. Nearly 10 per cent are interstate movements.

(a) Non-institutionalised civilians who were resident in Australia at the beginning and end of the survey year. (b) Excludes persons resident in Australia but with no usual residence at the beginning and/or end of the survey year. (c) Metropolitan areas exclude Canberra and Darwin prior to 1983.

The predominant reason for moving given by persons aged 15 and over at the 1986 Internal Migration Survey, particularly for intrastate movers, was housing. Of all intrastate movers, 63 per cent gave housing as the main reason. The next most quoted reason—employment—accounted for only 16 per cent of intrastate moves. On the other hand employment emerged as the main reason for interstate moves. It accounted for 53 per cent of interstate moves, whilst housing only accounted for 10 per cent.

The level of net interstate migration has been an important influence on the distribution of Australia's population amongst the States and Territories. Historically it has been much more important than differential fertility or mortality and in many periods more important than overseas migration. The table below presents estimates of net interstate migration for the thirteen intercensal periods between 1881 and 1981 and the subsequent financial years from 1981-82 to 1985-86. Net interstate migration tends to be volatile in nature and large gains and losses have been recorded by the States.

Sources: (a) Rowland, D.T. 1979: *Internal Migration in Australia*, Census Monograph Series, Australian Bureau of Statistics, Canberra. P. 20, refers only to movement of Australian born persons, estimated by use of intercensal survival method. (b) Di Iulio, O.B. *Post Censal Interstate Migration Estimates, 1966-81*. ABS Occasional Paper 1984/2. Based on Census results of Internal Migration adjusted for movement of persons aged 0-4 years. (c) Census data, 1976 and 1981.

New South Wales gained in population considerably from interstate migration between 1881 and 1921. Minimal gains were made between 1921 and 1947 but from then on the State has experienced substantial net losses, particularly to Queensland and, since the 1960s, to the Australian Capital Territory and Western Australia.

Victoria experienced high net losses during the depression of the 1890s and in the intercensal period 1901-1911. There was a period of large net gains between 1933 and 1947, but by 1961-1966 the State had reverted to net losses which still persist. Major losses occurred to Queensland in the twenty years from 1966 to 1986.

Queensland gained in all intercensal periods, excepting 1933-1947. This gain has been especially large since 1947, and in particular between 1971 and 1986.

South Australia has experienced fluctuating interstate migration, recording large losses between 1881 and 1911, noticeable gains in the 1947-1954 period, and gradual declines until, in 1966-1971, it had returned to large losses. The State gained again between 1971 and 1976 but since then has reverted to losses, although the extent of these has been considerably less than for New South Wales and Victoria.

Western Australia gained considerably from interstate migration between 1891 and 1911, but the following fifty years were generally a period of net losses. From 1961 however, Western Australia has recorded consistent net gains, mainly from Victoria, South Australia and, until 1983, from New South Wales.

Tasmania has a long history of losing population to other States. These losses were greatest between 1901 and 1933. Since 1983, however, the historical trend has been reversed and Tasmania has experienced small gains in net migration.

Northern Territory and Australian Capital Territory have consistently gained from interstate migration. The Australian Capital Territory in particular recorded very large gains in the seventeen years to 1976. Net migration for the Northern Territory between 1971 and 1976 should be interpreted in the light of the impact of Cyclone Tracy on Darwin in December 1974 which caused an evacuation of a large part of the Territory's population in December 1974 and early 1975. Net migration to both Territories slowed towards the end of the 1970s with Northern Territory receiving only small gains in the 1980s. The Australian Capital Territory lost population at the beginning of the 1980s, but since 1982 has experienced increasing gains.

During the fifteen years from 1966 to 1981, the flow of persons interstate increased, both numerically and in proportion to the population. Recent census data indicate that for the three five-year periods, 1966-71, 1971-76 and 1976-81, the number of interstate movers was 461,700, 569,500 and 651,200 respectively. This increase was evident for both males and females, with the masculinity ratio of interstate flows remaining virtually constant at 107.

INTERSTATE MOVERS BY AGE, MOBILITY RATES (a) AND SEX RATIOS (b), AUSTRALIA

Sex ratios—						
Interstate movers	107	106	107			
Total population	101	100	100			

(a) Interstate movers per 1,000 population of the same age group at end of period. (b) The number of males per 100 females.

Interstate mobility rates by age have revealed a clear and consistent life cycle pattern in the propensity of persons to move interstate. Looking at the five-yearly migration data, there was, initially, an above-average rate for the 5-9 year age group because of the high mobility of their parents. This was followed by a period of below average mobility in the early teenage years. Mobility was highest at ages 20-39 years, from whence it steadily declined with age. The highest mobility rates occurred at ages 25-29 years and the lowest at ages 65 and over. Females were generally less likely to move interstate than males, with differences being most pronounced during the child-rearing ages from 25 to 45 years.
