For each State and Territory the following tables are given:

1	Estimated resident population (1981 and 1984) and projections (1985 to 2021) by sex
2A	Estimated resident population (1981 and 1984) and projections (1985 to 2021) by age and sex - Series A
2B	Estimated resident population (1981 and 1984) and projections (1985 to 2021) by age and sex - Series B
2C	Estimated resident population (1981 and 1984) and projections (1985 to 2021) by age and sex - Series C
2D	Estimated resident population (1981 and 1984) and projections (1985 to 2021) by age and sex - Series D
3A	Number and percentage of population at selected ages, masculinity ratio, mean and median ages, dependency ratio - Series A
3B	Number and percentage of population at selected ages, masculinity ratio, mean and median ages, dependency ratio - Series B
3C	Number and percentage of population at selected ages, masculinity ratio, mean and median ages, dependency ratio - Series C
3D	Number and percentage of population at selected ages, masculinity ratio, mean and median ages, dependency ratio - Series D
4	Components of population change

## MAIN FEATURES

The projected population of Australia, on the assumptions detailed in Sections 2 and 4, ranges between 18.0 million and 18.3 million in 1996; 20.6 million and 21.7 million in 2011 and 22.0 million and 23.9 million in 2021, representing annual average growth rates over the whole projection period of between 0.9 per cent and 1.2 per cent.

While the number of persons in each age group is projected to increase between 1984 and 2021, the growth rates differ markedly resulting in a significant change in the age structure of the population. The population aged 0-14 increases from 3.7 million to between 4.2 million and 4.9 million, the population aged 15-44 increases from 7.3 million to between 8.8 million and 9.6 million, the population aged 45-64 increases from 3.0 million to between 5.7 million and 5.9 million, and the population aged 65 and over increases from 1.6 million to between 3.4 million and 3.5 million. These increases represent annual average growth rates of between 0.3 per cent and 0.7 per cent, 0.5 per cent and 0.7 per cent, 1.7 per cent and 1.9 per cent, and 2.1 per cent and 2.2 per cent respectively. The proportions of population in the younger age groups are projected to reduce; from 24.0 per cent to between 19.0 per cent and 20.5 per cent for those aged 0-14 and from 46.9 per cent to between 39.7 per cent and 40.2 per cent for those aged 15-44. For the older age groups, the proportions are projected to increase; from 19.1 per cent to between 24.7 per cent and 25.7 per cent for those aged 45-64, and from 10.1 per cent to between 14.6 per cent and 15.6 per cent for those aged 65 and over.

The projections for the States and Territories fall into two groups. New South Wales, Victoria, South Australia and Tasmania are projected to have annual average growth rates over the whole projection period of less than 1 per cent, and to have a decreased share of the national population, while Queensland, Western Australia, Northern Territory and the Australian Capital Territory are projected to have annual average growth rates greater than 1 per cent and to have an increased share of the national population.

Changes similar to those of the national population are expected to occur in the age structure of all States and Territories. The median age of the population, which was between 25.7 years (Northern Territory) and 31.4 years (South Australia) in 1984, is expected to increase by 6 to 8 years by 2021.

The projections are generally lower than those published in 1982 due mainly to lower assumed levels of fertility and overseas migration.

For a more detailed description of the results, see Section 3.

## 1 GENERAL

### 1.1 Introduction

This publication contains the results of projections of the populations of Australia, the States and Territories for the period 1984 to 2021. These projections replace the sets published in November 1982, "Projections of the Population of Australia, 1981-2021" (3204.0), and May 1983, "Projections of the Population of the States and Territories of Australia, 1981-2021" (3214.0).

Additional unpublished details can be obtained on microfiche on request.

Population projections are published by the ABS twice in each intercensal period and the next set is due for release early in 1988, after the results of the 1986 Population Census are available.

### 1.2 Objectives

As the central statistical agency, the ABS aims to provide a service to users of population projections and to those working in the field by regularly publishing sets of population projections and by developing a co-ordinated approach to projections work with and for other Government and private organisations.

Population projections published by the ABS are not intended as predictions or forecasts; they are illustrations of growth and change in the population which would occur if certain specified assumptions about future demographic trends are realised. While the selection of the assumptions is based on analysis of past demographic trends, both in Australia and overseas, and an assessment of their likely future movement, there is no certainty that any of the assumptions will or will not be realised.

The projections are intended to provide a base and framework for other organisations and individuals concerned with population projections. Alternative projections have been provided in recognition of the uncertainty of future movements in demographic trends, and to give users a range of options.

### 1.3 Development

The process of developing population projections involves research, analysis, consultation and computation. Analysis of demographic trends, research into the determinants of population growth and consultation with Government and academic institutions at both National and State levels are necessary to formulate the various assumptions and to ensure their general relevance for the projection period. Appropriate computer resources are required to perform the necessary calculations which result in the population projections.

All of these tasks are carried out by ABS staff. In-house computer facilities are used to generate the required projections and tabulations.

Consultative meetings were held in all States and Territories during July 1984 following which the assumptions for the 1984 to 2021 series of population projections were finalised. For fertility, overseas migration and interstate migration two alternative assumptions were selected, but only one assumption has been used for mortality.

## 2 METHODOLOGY

### 2.1 Projection techniques

There are a number of techniques which may be used for population projections, ranging from simple extrapolation through broad economic, social and time-series analysis to detailed component methods; the choice is largely dependent on the resources at hand and the availability of reliable data. The ABS uses the cohort-component method. This method begins with a base population for each sex by single years of age group and advances it year by year by applying assumptions regarding future mortality and migration. Assumed age-specific fertility rates are applied to the female populations of child-bearing ages to provide the new cohort of births. This procedure is repeated for each year in the projection period for each State and Territory and for Australia. The resulting population projections for each year for the States and Territories, by sex and single years of age are adjusted to sum to the Australian results.

### 2.2 Base population

For the set of population projections in this publication, the base is the preliminary estimated resident population at 30 June 1984.

### 2.3 Assumptions

#### 2.3.1 Fertility

Two sets of fertility assumptions have been used.

At the national level, for both assumptions, the total fertility rate declines linearly from 1,932 births per 1,000 women in 1983 to 1,930 in the year 1989. Beyond 1989 the two assumptions diverge:

- I - the total fertility rate established in 1989 is maintained for the remainder of the projection period,
- II - the total fertility rate gradually moves from the 1989 level to 2,110 (the level required for natural replacement of the population under the current mortality situation) in 1995 and remains at that level for the rest of the projection period.

For the States and Territories, the differences in total fertility rate from the Australian level in 1983 are reduced until, in 1989, the rate for the Northern Territory is 10 per cent higher than the Australian level, for Queensland 5 per cent higher and for Victoria and South Australia 5 per cent lower. The rates for the remaining States and Territory equal the Australian level. Beyond 1989, for both alternatives, the total fertility rates for the States and Territories are assumed to change in the same way as the national total fertility rate.

Table 2.1 summarises the projected total fertility rates.

Background analysis and details of the rationale behind the selection of the fertility assumptions are presented in Section 4.1.

TABLE 2.1 TOTAL FERTILITY RATES(a), STATES AND TERRITORIES,  
1983 (ACTUAL) AND 1984 TO 2021 (PROJECTED)

YEAR	NSW	VIC	QLD	SA	WA	TAS	NT	ACT	AUSTRALIA

1995+	2110	2110	2110	2110	2110	2110	2110	2110	2110

(a) Rate per 1,000 women.

### 2.3.2 Mortality

Only one assumption for mortality has been used. For Australia, the States and Territories, the average Australian age-sex-specific mortality rates in 1981 to 1983 (assumed to represent the 1982 level) are used as a base. For each year to 1987, the mortality rates are reduced according to the short-term rates of decline shown in Table 2.2. For the years 1988 to 1995, the long-term rates of decline are applied to the 1987 rates and the levels achieved in 1995 are assumed to continue for the rest of the projection period. Table 2.3 shows actual (average 1981 to 1983) and projected mortality rates for Australia for selected ages and years.

TABLE 2.2 PROJECTED SHORT AND LONG-TERM PERCENTAGE ANNUAL CHANGES IN MORTALITY RATES, AUSTRALIA, 1982 TO 1987 AND 1988 TO 1995

Age	Short-term (1982 to 1987)		Long-term (1988 to 1995)	
	Males	Females	Males	Females
0	-5.9	-5.3	-2.5	-2.5
10	-2.8	-3.5	-2.1	-2.4
20	-1.0	-1.6	-1.0	-1.3
30	-1.4	-2.8	-0.9	-1.8
40	-1.9	-3.4	-0.9	-1.5
50	-2.6	-3.3	-0.9	-1.2
60	-2.5	-3.1	-0.6	-1.1
70	-2.4	-3.0	-0.4	-1.1
80	-2.2	-3.0	-0.3	-1.1

Details of the analysis leading to this assumption are given in Section 4.2.

70	20.60	17.69	16.19
80	60.38	51.85	47.46

### 2.3.3 Overseas migration

Two assumptions for overseas migration have been used. In the short-term, to 1987, the net gain each year has been set at 50,000 (75,000 arrivals and 25,000 departures) for both assumptions. For the remainder of the projection period, the assumptions are:

- I - net gain of 75,000 (100,000 arrivals and 25,000 departures) annually,
- II - net gain of 100,000 (130,000 arrivals and 30,000 departures) annually.

The distribution by State and Territory of both arrivals and departures has been assumed to be the same and is given in Table 2.4. The age-sex distributions, however, have been based on the distributions of permanent arrivals and departures observed in 1981 to 1983 for each State and Territory.

TABLE 2.4 PERCENTAGE SHARE OF OVERSEAS MIGRATION, STATES AND TERRITORIES

	NSW	VIC	QLD	SA	WA	TAS	NT	ACT	AUSTRALIA
Arrivals	37.8	23.3	15.0	6.5	13.0	1.2	1.2	2.0	100.0
Departures	37.8	23.3	15.0	6.5	13.0	1.2	1.2	2.0	100.0

Details of the analysis leading to these assumptions can be found in Section 4.3.

#### 2.3.4 Interstate migration

The two assumptions used for interstate migration are as follows:

- I - small net gains and losses for the States and Territories,
- II - large net gains and losses for the States and Territories.

Details are given in Table 2.5.

TABLE 2.5 PROJECTED NET INTERSTATE MIGRATION, STATES AND TERRITORIES

Year	NSW	VIC	QLD	SA	WA	TAS	NT	ACT
ASSUMPTION I								
1984-85	-9500	-4000	8500	-1000	2000	-	1500	2500
1985+	-7500	-5000	9000	-	2500	-500	1000	500
ASSUMPTION II								
1984-85	-13500	-4500	12000	-2000	3000	-1000	2000	4000
1985-86	-15000	-6000	15000	-2000	4500	-1500	2000	3000
1986+	-15000	-8000	17000	-2000	4500	-1500	2000	3000

For both assumptions, the age-sex distributions of arrivals and departures for each State and Territory are based on the average of the similar distributions for 1982 and 1983.

Further analysis leading to these assumptions is contained in Section 4.4.

#### 2.3.5 Summary

The various alternative assumptions are summarised in Table 2.6 for ease of reference.

TABLE 2.6 SUMMARY OF ASSUMPTIONS

Component	Period	Assumption
Mortality	to 1987	. Average 1981 to 1983 levels adjusted annually by short-term rates of decline. State variations maintained
	1988 to 1995	. 1987 levels adjusted annually by long-term rates of decline. State variations maintained
	1996 to 2021	. 1995 levels maintained
Fertility I	to 1989	. Total fertility rate for 1983 reduced linearly to 1,930 for Australia with State variations
	1990 to 2021	. 1989 levels maintained
Fertility II	to 1989	. Total fertility rate for 1983 reduced linearly to 1,930 for Australia with State variations
	1990 to 1995	. All levels changed linearly to 2,110
	1996 to 2021	. 1995 levels maintained
Overseas migration I	1984-85	. Net migration annually of 50,000 for Australia
	to 1986-87	
	1987-88	. Net migration annually of 75,000 for Australia
Overseas migration II	to 2020-21	
	1984-85	. Net migration annually of 50,000 for Australia
	to 1986-87	
	1987-88	. Net migration annually of 100,000 for Australia
Interstate migration I	to 2020-21	
	1984-85	. Small net flows - absolute sum annually of 29,000
	1985-86	. Small net flows - absolute sum annually of 26,000
	to 2020-21	
Interstate migration II	1984-85	. Large net flows - absolute sum annually of 42,000
	1985-86	. Large net flows - absolute sum annually of 49,000
	1986-87	. Large net flows - absolute sum annually of 53,000
	to 2020-21	

## 2.4 Description of the series

Based on the possible combinations of the alternative assumptions, there are 4 series for Australia and 8 for the States and Territories as shown below.

<u>Series</u>	<u>Assumption</u>	<u>Series</u>	<u>Assumption</u>
A	Mortality Fertility I Overseas migration I Interstate migration I	A1	Mortality Fertility II Overseas migration I Interstate migration I
B	Mortality Fertility I Overseas migration I Interstate migration II	B1	Mortality Fertility II Overseas migration I Interstate migration II
C	Mortality Fertility I Overseas migration II Interstate migration I	C1	Mortality Fertility II Overseas migration II Interstate migration I
D	Mortality Fertility II Overseas migration II Interstate migration II	D1	Mortality Fertility I Overseas migration II Interstate migration II

Only Series A, B, C and D are published in this bulletin. Series A and D result in the minimum and maximum projected populations for Australia under the alternative assumptions and Series B and C provide comparisons for alternate levels of overseas and interstate migration. The remaining 4 series (A1, B1, C1 and D1) are not published but are available on microfiche from the ABS.

Because of the construction of the assumptions there is some commonality among the series. For Australia, Series A and B are identical as are A1 and B1, C and D1, and D and C1. For the States and Territories, projections for the first three years, 1985 to 1987, are identical for Series A, C, A1 and C1, and for Series B, D, B1 and D1. For Australia, all series are identical for the first three years.

### 3. SUMMARY OF PROJECTIONS

#### 3.1 Total population

The total population of Australia is projected to increase from 15.5 million in 1984 to 22.0 million by 2021 under Series A and B assumptions, to 23.1 million under Series C assumptions and to 23.9 million under Series D assumptions (Figure 3.1). The annual average growth rates over the period are 0.9 per cent, 1.1 per cent and 1.2 per cent respectively. The projected populations for 1991, 2001 and 2011 are given in Table 3.1 along with average annual growth rates for the intervening periods.

TABLE 3.1 PROJECTED POPULATION AND GROWTH RATES(a), AUSTRALIA, SELECTED YEARS

	Series A and B		Series C		Series D	
	Persons ( '000)	Growth rate (%)	Persons ( '000)	Growth rate (%)	Persons ( '000)	Growth rate (%)
1984	15543.6		15543.6		15543.6	
1991	16937.7	1.23	17041.6	1.31	17049.4	1.32
2001	18917.4	1.11	19309.8	1.25	19530.4	1.36
2011	20561.1	0.83	21274.5	0.97	21746.0	1.07
2021	22029.1	0.69	23095.1	0.82	23902.5	0.95

(a) Average annual growth rate

For all series, the projected age structure in 2021 shows a marked ageing of the population over the projection period (Figure 3.2). Although the proportion of the population of working age (15-64) remains about 65 per cent, the proportion of children aged 0-14 decreases from 24 per cent to 20 per cent while the proportion of persons aged 65 and over increases from 10 per cent to 16 per cent between 1984 and 2021. Within the working age population a similar shift occurs with the proportion aged under 45 declining from 47 per cent to 40 per cent and the proportion aged 45 and over increasing from 19 per cent to 25 per cent during the same interval. The median age of the population increases from 30.5 years in 1984 to between 36.5 (Series D) and 38.2 (Series A and B) in 2021.

#### 3.2 Births and deaths

Births are projected to increase from the 1984-85 level of 250,000. A large increase to 340,000 in 2020-21 is projected under Series D assumptions while Series A and B assumptions result in only a modest increase to 280,000 births in 2020-21. The crude birth rate however shows a different pattern. For Series A and B, the rate declines from 15.7 per 1,000 population in 1984-85 to 12.8 per 1,000 in 2009-10 and stabilizes at that level for the remainder of

FIGURE 3.1 PROJECTED POPULATION OF AUSTRALIA, SERIES A TO D, 1984 TO 2021

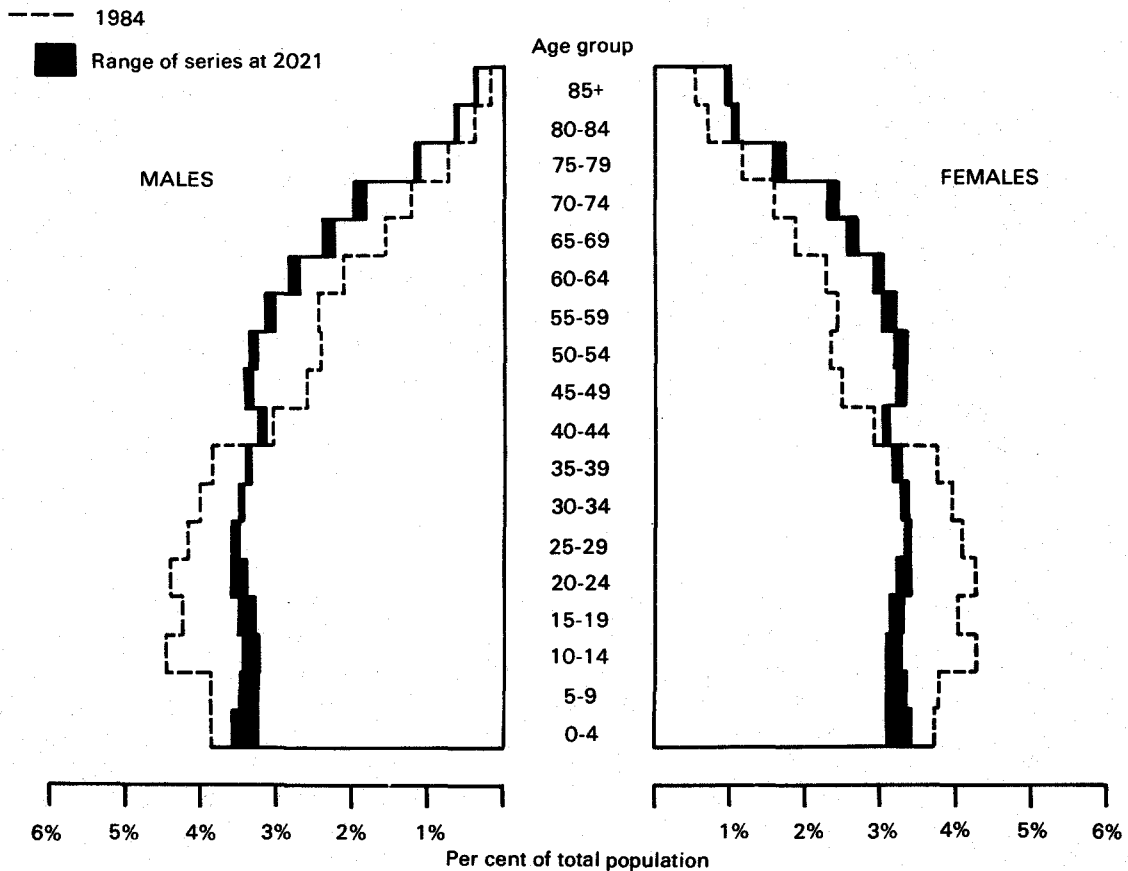

FIGURE 3.2 ACTUAL (1984) AND PROJECTED (2021) POPULATION AGE-SEX STRUCTURE, AUSTRALIA

the projection period. For Series D, the crude birth rate increases to 16.1 per 1,000 population in 1994-95 followed by a decline to 13.9 per 1,000 in 2008-09. For the rest of the projection period, a slight increase in the crude birth rate is recorded (Figure 3.3). The number of births and birth rates for Series C lie between the other series.

Despite declining mortality rates, the projected number of deaths for all series increases over the whole projection period reaching about 210,000 in 2020-21. The crude death rate also increases steadily from 7.3 per 1,000 population in 1984 to between 9.4 per 1,000 (Series D) and 9.8 per 1,000 (Series A and B) in 2020-21 (Figure 3.4).

### 3.3 Population of school and tertiary education age

#### 3.3.1 Primary and secondary school age population

The school age population (persons aged 5-16) is projected to increase from 3.07 million in 1984 to between 3.35 million (Series A and B) and 3.88 million (Series D) in 2021. The pattern of this increase is shown in Figure 3.5. For Series A and B, the number of school age children declines slightly to 2.96 million in 1991 and then increases at an annual average rate of 0.7 per cent to 3.33 million in 2007. For the next 10 years of the projection period there is a slight decline to 3.31 million followed by a slight increase for the last four years (2018 to 2021). The pattern for Series D is similar but the period of increase is longer, from 1990 to 2010 and the rate of increase during this period averages 1.2 per cent per year. The number of school age children reaches 3.76 million in 2010 before stabilizing for four years and then increasing again for the remainder of the projection period.

#### 3.3.2 Tertiary education age population

The number of people of tertiary education age (17-22) is projected to increase from 1.58 million in 1984 to between 1.73 million (Series A and B) and 1.97 million (Series D) in 2021. The pattern for all series shows an increase to 1991 (at an annual average rate of 0.8 per cent for Series A and B and 0.9 per cent for Series D), a decline to 1998 (at an annual average rate of 1.5 per cent for Series A and B and 1.3 per cent for Series D), a further increase to 2017 (0.8 per cent for Series A and B and 1.3 per cent for Series D) and finally a slight decline for the last four years of the projection period (Figure 3.6).

### 3.4 Population of working age

#### 3.4.1 Population of young working age (15-24)

The population of young working age is projected to increase from 2.64 million in 1984 to between 2.88 million (Series A and B) and 3.29 million (Series D) in 2021. The pattern is similar to that for persons of tertiary education age and is shown in Figure 3.7.

#### 3.4.2 Population of prime working age (25-49)

The population of prime working age is projected to increase sharply between 1984 and 1996 at an annual average rate of 1.9 per cent for Series A and B and 2.1 per cent for Series D. The rate of increase then reduces markedly for the remainder of the projection

FIGURE 3.3 PROJECTED BIRTHS AND CRUDE BIRTH RATES, SERIES A TO D, AUSTRALIA, 1984 TO 2021

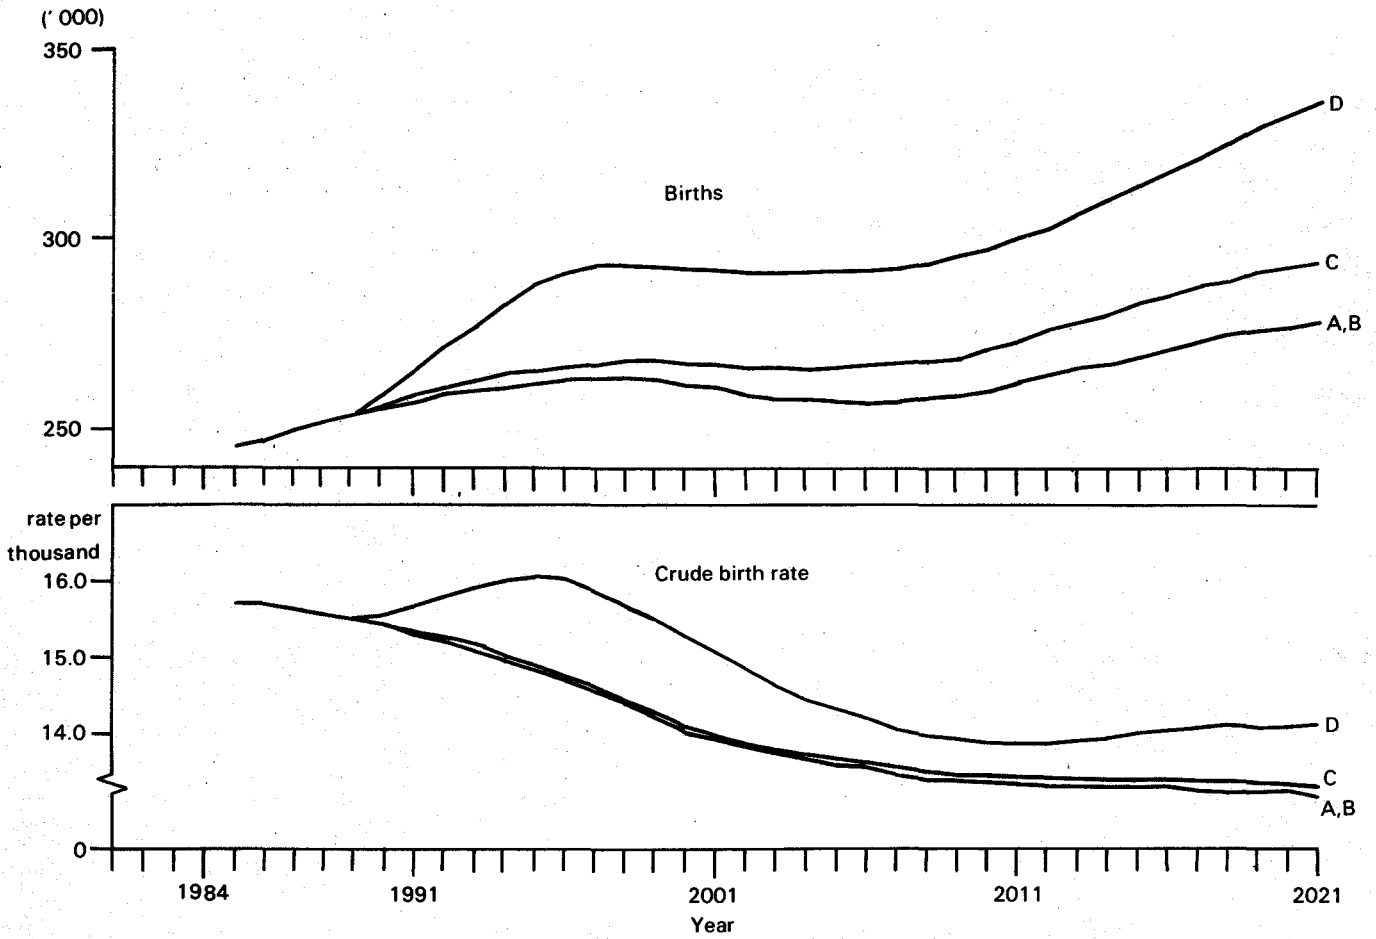

FIGURE 3.4 PROJECTED DEATHS AND CRUDE DEATH RATES, SERIES A TO D, 1984 TO 2021

(a) The differences between the number of deaths under Series C and Series D assumptions are too small to be plotted separately.

**FIGURE 3.5 PROJECTED POPULATION OF SCHOOL AGE (5-16), SERIES A TO D, AUSTRALIA, 1984 TO 2021**

**FIGURE 3.6 PROJECTED POPULATION OF TERTIARY EDUCATION AGE (17-22), SERIES A TO D, AUSTRALIA, 1984 TO 2021**

**FIGURE 3.7 PROJECTED POPULATION OF YOUNG WORKING AGE (15-24), SERIES A TO D, AUSTRALIA, 1984 TO 2021**

**FIGURE 3.8 PROJECTED POPULATION OF PRIME WORKING AGE (25-29), SERIES A TO D, AUSTRALIA, 1984 TO 2021**

period to an average of 0.3 per cent per year for Series A and B and 0.5 per cent per year for Series D. The projections result in between 7.4 million (Series A and B) and 7.9 million (Series D) persons aged 25-49 in 2021 (Figure 3.8).

#### 3.4.3 Population of older working age (50-64)

The population of older working age is projected to show a steady increase after 1991 of between 2.1 per cent (Series A and B) and 2.2 per cent (Series D) per year, reaching 4.2 million (Series A and B) or 4.3 million (Series D) by 2021. In the earlier years, little increase from the 1984 level of 2.4 million is projected (Figure 3.9).

#### 3.5 Population of pensionable age

The population of pensionable age (males aged 65 and over and females aged 60 and over) shows the largest increase of any population group over the whole projection period, from 1.9 million in 1984 to between 4.1 million (Series A and B) and 4.2 million (Series D) in 2021. This represents an average annual increase of over 2 per cent; 2.8 per cent for the 7 years to 1991, and 1.6, 2.0 per cent and 2.4 per cent for the subsequent 3 decades (Figure 3.10).

#### 3.6 Population of voting age

The population of voting age (18 and over) is projected to increase steadily over the whole projection period from 11.0 million in 1984 to between 17.0 million (Series A and B) and 18.0 million (Series D) representing an average growth rate of between 1.2 per cent and 1.3 per cent per year (Figure 3.11).

#### 3.7 Dependency ratio

The dependency ratio is the ratio of the dependent population, i.e. those aged 0-14 and 65 and over, to the population of working age (aged 15-64 years). The projected dependency ratio varies between 48.1 and 54.1 per 100 population of working age and fluctuates as shown in Figure 3.12. For all series, there is an initial decline to 1989 followed by an increase to 1996 (Series A, B and C) or 1997 (Series D), a decline to 2009 (Series A, B and C) or 2011 (Series D), and finally an increase for the remainder of the projection period to reach a maximum value in 2021 of 52.3 for Series C, 52.8 for Series A and B and 54.1 for Series D. The minimum dependency ratio under Series A, B and C assumptions occurs in 2009 and is 48.3 for Series A and B and 48.1 for Series C. Under Series D assumptions the minimum value of 50.1 occurs in 1989.

#### 3.8 State and Territory summary

Table 3.2 summarises the projected change in population size, growth rate, distribution within Australia and median age of population that would occur for each State and Territory during the projection period 1984 to 2021.

**FIGURE 3.9 PROJECTED POPULATION OF OLDER WORKING AGE (50-64), SERIES A TO D, AUSTRALIA, 1984 TO 2021**

### 3.8.1 Total population and projected growth

The projected total population of each State and Territory shows a faster rate of growth during 1984 to 2001 than during 2001 to 2021. The growth rates for New South Wales, Victoria, South Australia and Tasmania are lower than the national average for all series of projections while the growth rates for the other States and Territories are higher. The highest growth rate occurs for the Northern Territory and the lowest for Tasmania during each of the two periods 1984 to 2001 and 2001 to 2021. For the other States and Territory the growth rates are highest for the Australian Capital Territory, followed by Western Australia, Queensland, Victoria, New South Wales and South Australia in that order. The range of projected population sizes for each State and Territory based on the four series of the projections is shown in Table 3.3.

TABLE 3.3 RANGE OF POPULATION SIZE, STATES AND TERRITORIES,  
SELECTED YEARS  
(Millions)

Year	NSW	VIC	QLD	SA	WA	TAS	NT	ACT
1984	5.4	4.1	2.5	1.4	1.4	0.44	0.14	0.25
2001	6.3-6.6	4.7-4.9	3.3-3.5	1.5-1.6	1.8-1.9	0.48-0.51	0.21-0.24	0.34-0.40
2021	7.0-7.7	5.2-5.7	4.1-4.6	1.6-1.8	2.3-2.6	0.48-0.56	0.30-0.37	0.43-0.59

### 3.8.2 Population distribution

The State and Territory distribution of the population of Australia is projected to change with New South Wales, Victoria, South Australia and Tasmania losing population share and the remaining States and Territories gaining population share. The largest gains for all series occur in Queensland which increases its share of population from 16.1 per cent to between 18.2 and 19.8 per cent by 2021. The largest losses on the other hand occur in Victoria for Series A and C (2 percentage points) and in New South Wales for Series B and D (2.9 and 2.7 percentage points respectively).

### 3.8.3 Median age

The median age of the population is projected to increase in all States and Territories between 1984 and 2021. For Series A and C the greatest increase in median age (9.8 years for Series A and 9.4 years for Series C) occurs in the Australian Capital Territory and the smallest increase (7.1 years for Series A and 6.6 years for Series C) occurs in New South Wales. For Series B and D, the greatest increase in median age (11.4 years for Series B and 9.7 years for Series D) occurs in Tasmania and the smallest increase occurs in the Northern Territory for Series B (6.2 years) and New South Wales for Series D (5.7 years).

## 4 BACKGROUND TO THE ASSUMPTIONS

### 4.1 Fertility

#### 4.1.1 Introduction

Fertility in Australia declined dramatically during the 1970s. The total fertility rate fell from 2,870 births per 1,000 women in 1971 to its lowest level of 1,894 in 1980. A slight increase was recorded in 1981 but the rate fell again to a level of 1,932 in 1983. This reduction in fertility occurred amidst the demographic, social, economic and attitudinal changes of the 1970s which individually or collectively influenced fertility and its components during this period. Child bearing shifted to higher ages and was concentrated in a narrower band of ages of women; the contribution of ex-nuptial births to total fertility increased; and third and higher order births were curtailed with the development of a two-child family norm. The changing life style of couples and increased incidence of 'defacto' living arrangements also had their impact on depressing fertility. State and Territory variations in fertility narrowed.

This section provides background information on fertility transition and the reasons behind the development of the alternative fertility assumptions for Australia, the States and Territories.

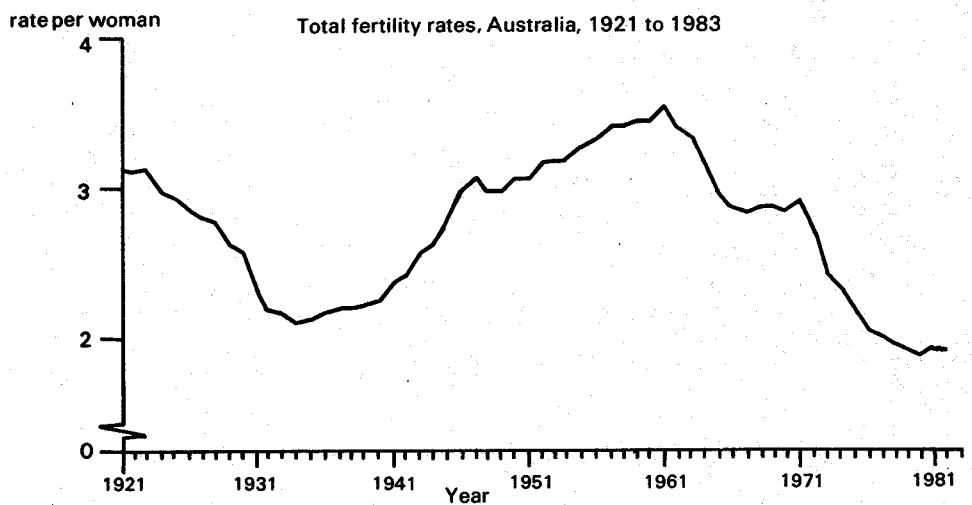

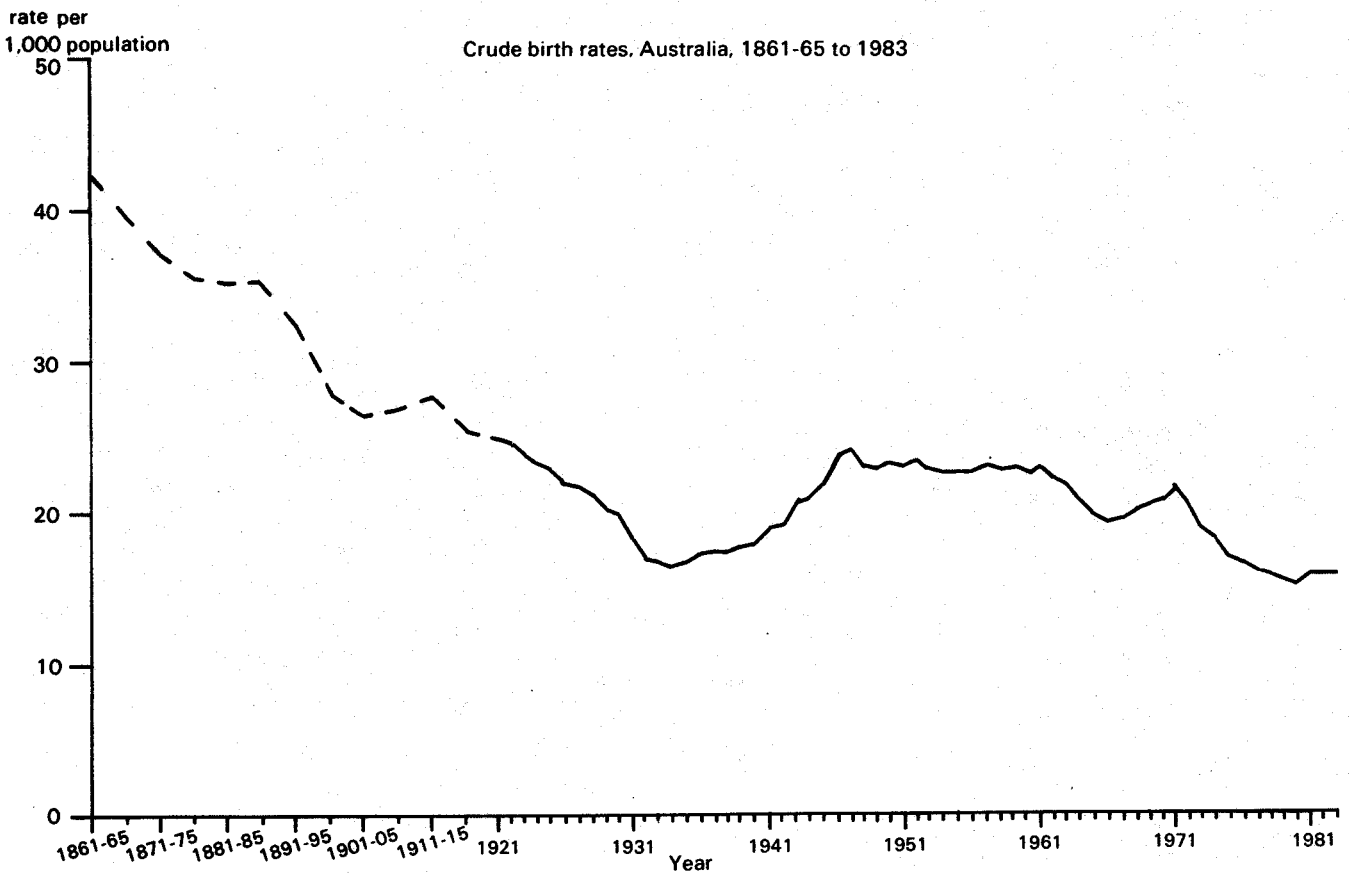

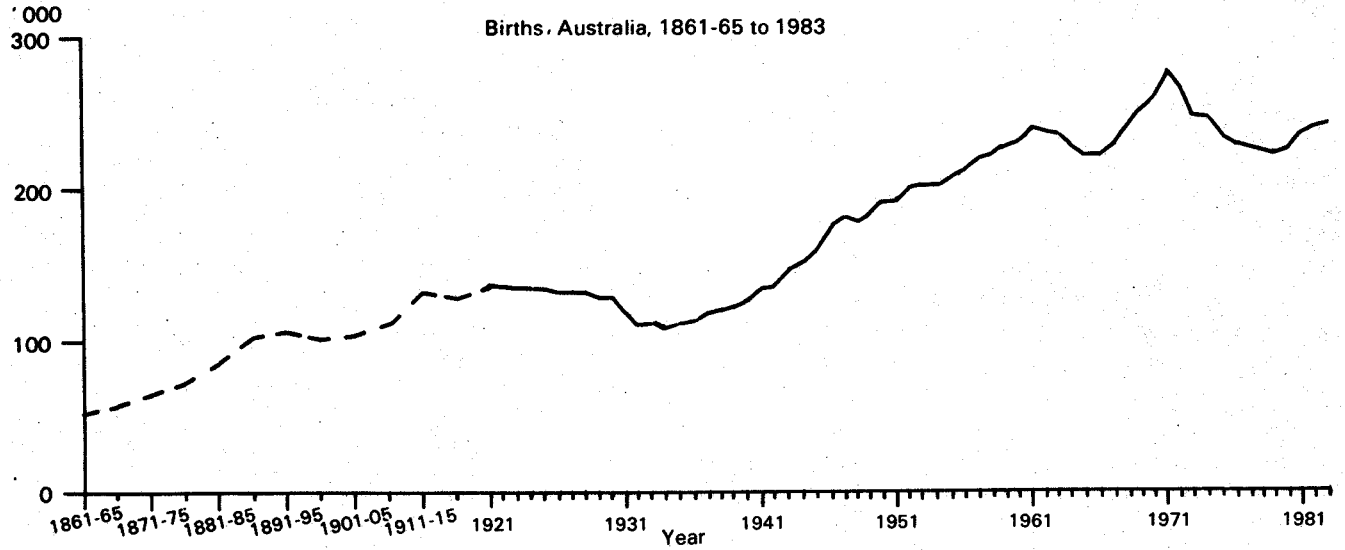

#### 4.1.2 Trends in cross-sectional fertility

The crude birth rate in Australia has been declining steadily since the 1870s, with brief periods of increase from 1904 until 1912, from 1934 to 1947 and from 1966 to 1971. In 1934 the rate was 16.4 per 1,000 population, the lowest on record until that time. The rate then increased in the following years and reached a post-war peak level of 24.1 in 1947. From then on until 1962 the rate fluctuated within a narrow range although above 22 per 1,000 throughout. Thereafter, the rate dropped between 1961 and 1966, increased between 1966 and 1971 to reach the level attained in 1963 (21.6 per 1,000), and plummeted between 1971 and 1975. The rate in 1975 was 20 per cent lower than that for 1971. This drop continued until the rate reached its lowest level of 15.3 per 1,000 in 1980. The early 1980s saw a slight rise - the rate in 1983 was 15.8 per 1,000 (Figure 4.1).

As opposed to the long-term decline in the birth rate, the number of births registered generally followed an increasing trend until 1961, primarily as a function of the increase in the population. Subsequently, the number of births declined in each year between 1961 and 1965, and increased thereafter, reaching a peak of 276,362 births in 1971. The number of births in each year then fell until 1979 (223,129 births), and rose to 242,570 in 1983. The dramatic fluctuations in the absolute number of births since 1961 have occurred despite the fact that the population was increasing at all times during the entire period until 1983 (Figure 4.1).

The total fertility rate (TFR), which is unaffected by the age-sex composition of the population, is an improved summary measure of fertility. The TFR showed an identical trend to that followed by the crude birth rate except for the years 1949 to 1960 during which it rose uninterruptedly (Figure 4.1).

**FIGURE 4.1 BIRTHS, CRUDE BIRTH RATES AND TOTAL FERTILITY RATES, AUSTRALIA, 1861 TO 1983**

#### 4.1.3 Recent trends in the components of total fertility

4.1.3.1 Age-specific fertility rates - An analysis of the trends in age-specific fertility rates between 1971 and 1983 reveals that the rates have declined in all age groups, but the reduction is most noticeable in the two younger (15-19 and 20-24) and three older (35-39, 40-44 and 45-49) age groups (Table 4.1). From about 1978 onwards, however, the rates in the age group 30-39 have increased, which is probably a reflection of the 'making up' of the fertility of these women deferred in the 1970s. The rate in 1983 in the age group 30-34, for example, was 11 per cent higher than that recorded in 1978.

Women aged 25-34 contributed 50.8 per cent of total fertility during 1971 to 1975. This share increased to 58.9 per cent in 1983. The contribution to total fertility by women aged 15-24 declined from 40.6 per cent during 1971 to 1975 to 33.5 per cent in 1983. (Table 4.1)

4.1.3.2 Median age of women at first marriage and median age of mothers at birth of child(a) - The median age of women at first marriage and the median age of mothers at birth of child have risen. (Table 4.2). The greatest increase has occurred in the median age of mothers at birth of the first child, from 23.7 years in 1971 to 26.1 years in 1983. The median age of mothers of ex-nuptial births has also risen.

4.1.3.3 Birth order-specific fertility rates - A clearer picture of the changing patterns of fertility can be seen through an examination of the ex-nuptial and nuptial fertility rates, the latter classified by birth order of children. Unfortunately, birth order of ex-nuptial births is not collected in Australia. However, the age structure of mothers of ex-nuptial births is young (in 1983, median age of mothers was 22.9 years as opposed to 27.2 years for all births) which indicates that ex-nuptial births mostly represent first order births. Table 4.3 shows that the contribution to total fertility from higher order nuptial births (three plus) has declined, whereas that from first births has increased. Although the contribution by second births declined in the 1970s, it appears to have stabilized in the 1980s.

The greatest change has occurred in ex-nuptial fertility. In 1971, ex-nuptial fertility was 8.7 per cent of total fertility. This rose each year to 14.5 per cent in 1983. As a consequence, the contribution from nuptial fertility to total fertility was reduced from over 90 per cent during 1971 to 1975 to 85.5 per cent in 1983.

The combined share of first and second order births amounted to over 65 per cent of total fertility in the mid 1970s. This has declined ever since and was 63.4 per cent in 1983. This decline appears to be related to the rise in ex-nuptial fertility. The contribution of third and higher order births to total fertility declined from 28.3 per cent in 1971 to 1975 to 21.9 per cent in 1983. This is an indication that couples are moving toward a two-child family norm.

---

4.1.4 Trends in cohort fertility

The TFR for a given year represents the contribution to fertility in that year by women belonging to different generations, i.e. those women born in different years and who therefore were at various stages of their reproductive life. The generation fertility rates fluctuate less and give a clearer indication of the long-term trend in fertility.

(a) Per 1,000 women

The fertility experience of Australian women born from 1841 to 1956 is presented in Table 4.4. It is of interest that the generation TFR's never fell below the replacement level (2,110 at the current level of mortality), as the annual TFR's did during the depression years of the 1930s and from the mid 1970s.

Table 4.4 shows that the number of births dropped from an average of over six per married women born in 1841 to 1846 to just over three births to those married women born at the end of the nineteenth century. The generations born during the first two decades of the present century experienced a further decline in fertility averaging under three births in their lifetime. Most of the explanations of this fertility transition in the late nineteenth century lay stress on the value of children and the desire of families to raise their standards of living through restricting and delaying marriage, limiting the numbers of children and promoting better education among children (Caldwell, 1982; McDonald, 1983). The adverse economic conditions of the 1930s ensured a continuation of the fertility decline. Over 20 per cent of the women born between 1861 and 1908 remained childless.

The rise in fertility during the two decades following the Second World War was largely the experience of women born between 1918 and 1943. Overall, the extent of marriage among these women was high and a declining proportion remained childless. Other social changes occurred during the 1950s and 1960s which contributed to the increase in fertility in this period; the age at first marriage of women declined, the proportion ultimately marrying increased, the deferred births of the war years were made up, an increase in ex-nuptial fertility was recorded, post-war immigration favoured younger migrants, and the workforce participation of married women was 'heavily discouraged' (McDonald, 1983).

#### 4.1.5 Explanations for fertility decline

The transition to a decline in fertility from the early 1960s to the present has been largely attributed to the experience of women born after the Second World War. Explanations of the decline in fertility are numerous and diverse and have been documented in the recent literature on Australian fertility (National Population Inquiry, 1975 and 1978; Ruzicka and Choi, 1981; Caldwell, 1982; United Nations, 1982(1); Hugo and Wood 1983; McDonald, 1983). In the following paragraphs a summary of these explanations is presented broadly in terms of demographic, economic, social and attitudinal changes that have individually or collectively contributed to the reproductive performance of women at the present time.

Factors such as the decline in the mortality rate, immigration to Australia over the past three decades and the ageing of the post-war baby boom cohorts have meant that the proportion of women in the reproductive ages has increased. As a consequence of this, even with the stable TFR recorded during 1966 to 1971, the number of births registered during those years continued to rise.

The economic and social changes that occurred during the 1970s had a profound effect on the attitudes of women to marriage and child bearing. Such changes were not unique to Australia but were taking

## NOTES:

- A Average number of children born to all marriages derived from all married women surviving at the time of the 1921 Census of Australia (Ruzicka and Caldwell, 1977, p.153)
- B Average number of children born to existing marriage only (Ruzicka and Caldwell, 1977, p.153)
- C Total fertility rate divided by the proportion of the generation who ever married during their lifetime. Proportions ever married derived from column D of the table. Total fertility rates for birth years 1893 to 1913 from Ruzicka and Caldwell, 1977, p.158. Total fertility rates for birth years 1913 to 1953 from Ruzicka and Choi (1981, p.114). Total fertility rates for birth years 1954 to 1956 based on McDonald's estimate.
- D Derived from Census data on proportions never married among women aged 45-49 or above for all generations born before 1938. Age group 45-49 is used as first choice if the data are available. For generations born before 1861, higher age groups are used according to the age of the generation at the time of 1911 Census. For those born from 1938 onwards, estimates have been made on the basis of experience to 1982.
- E Generations 1841 to 1876 from Appendix A, volume 1, Census of the Commonwealth of Australia, 1911, p.326. Generations 1908 to 1943 from the microfiche tables of the 1981 Census. For this latter set of data, it has been assumed that issue not stated should be distributed on a pro-rata basis. For generations from 1943 onwards, the values shown are rough estimates made by McDonald on the basis of fertility experience to 1982. Generations born from 1877 to 1908 present a problem as the data on children in the censuses which cover these generations refer only to children of the existing marriage. Further the extent of not stated issue varies greatly from census to census. McDonald made estimates based on the available fertility data, particularly the 1954 Census, and the proportions who never married. These estimates are enclosed in brackets to indicate their low level of reliability.

Source: Adapted from McDonald (1983).

place simultaneously in other industrialized nations. Oral contraceptives introduced in Australia in the early 1960s, a wider acceptance of sterilization and increased availability of abortion brought about a revolution in the family building patterns of couples. Not only was the arrival of unplanned children reduced, but the spacing and timing of births were regulated in such a way as not to conflict with the wider roles of women which developed during this period.

The economic recession and the rise in the cost of owning a home may also have caused women to accept alternative roles and life styles in society as opposed to their traditional role of motherhood.

The liberalization of social attitudes toward sex before marriage, ex-nuptial fertility and pre-marital conception, and improvement in contraceptive technology contributed to new life styles and attitudes to marriage and fertility. Ex-nuptial fertility rose as did the age at first marriage. The incidence of pre-marital pregnancy declined (as women who became pregnant saw no need to contract a 'forced' marriage because of pressure from society), couples postponed the arrival of the first birth and reduced the occurrence of third and higher order births. Fertility was restricted to a narrow age band. Overall, women restricted their childbearing and the incidence of life-time childlessness amongst them increased.

Various other developments contributed to the present patterns of women's fertility behaviour in Australia. These included the trend towards higher levels of education and the changing status of women in society, liberalized divorce laws, availability of maternity leave for women, particularly in the public sector, equal job opportunities and legislation against sex discrimination. Such movements changed the outlook of women and influenced their reproductive behaviour.

#### 4.1.6 Debate on future fertility levels

There is considerable debate in the literature as to how the present attitudes and behaviour of women in Australia and the developed world in general will shape fertility trends in the future. It may be argued that the TFR in the early 1980s reached its lowest point, mainly under the influence of the depressed economic climate which persisted from the 1970s, and that with economic recovery fertility will rise again, duplicating fertility experience of the post-depression years of the 1930s. Alternatively, it may be argued that the present changed attitudes and behaviour of women will not be reversed, and women will continue to want roles alternative or additional to motherhood, ultimately achieving a family size that will be lower than their natural replacement. In the process, there may occur changes in the spacing and timing of births, but the overall fertility levels will probably remain low. Support for such an argument comes from the two surveys conducted in Melbourne in 1971 and 1977 by the Australian National University, the two Birth Expectation Surveys conducted in 1976 and 1979 by the Australian Bureau of Statistics, and finally a survey done in 1981-82 by the Institute of Family Studies (McDonald 1983), which all reveal that there is a strong preference for a two-child family in Australia. The average number

of children desired varies according to the age and marital status of the respondents, the actual number of children they already have and the sex of these children. Based on the Institute of Family Studies Survey findings, McDonald (1983) argues that 'many couples are indecisive and ambivalent about future child bearing' and even in the situation of economic recovery to a level reached in the mid 1960s, women would combine 'childbearing with workforce participation at even greater levels than at present, and in the long term '20 per cent or more of women will not have a birth and only a small proportion will have three or more children'.

#### 4.1.7 Fertility projections for Australia

The foregoing discussion indicates that the TFR in Australia will probably remain below a level of 2,000 births per 1,000 women at least for the next 5 to 10 years. Given the uncertainties of the future, two alternative fertility assumptions have been made:

- I - that a new low level of total fertility will be achieved in year 1989 which will be the result of the current movements in the components of fertility, and that this level will prevail in the future,
- II - that having reached the 1989 level, fertility will start rising and in the year 1995 and beyond will attain a natural replacement level of 2,110. This alternative illustrates the long-term impact that continued fertility at replacement level would have on population size.

The TFR for 1989 has been determined on the basis of the assumed fertility rates for various nuptial (by birth order) and ex-nuptial births.

As outlined above, time-trend analysis of the components of fertility has indicated a rise in the incidence of ex-nuptial fertility, near stabilization of first and second order births fertility, and a decline in third and higher order births fertility. The assumed 1989 rates are based on an extrapolation of these trends. These rates along with the interpolated rates for 1984 to 1988, and for 1990 to 1995 are presented in Table 4.3.

The assumed ex-nuptial and nuptial (by birth order) fertility rates give rise to a total fertility rate of 1,930 for Australia in 1989. These rates assume the contribution from ex-nuptial fertility to total fertility to rise from 14.5 per cent in 1983 to 16.5 per cent in 1989, from first and second order nuptial births to be almost constant at 63.5 per cent (63.4 per cent in 1983) and from third and higher order nuptial births to decline from 22.1 per cent in 1983 to 20.0 per cent in 1989. These contributions are assumed to be constant after 1989.

The age-specific fertility rates are then obtained by distributing ex-nuptial and nuptial (by birth order) total fertility rates over the five-year age groups. The age distributions of birth order-specific fertility rates as observed in 1983, are assumed to apply during the entire projection period, except for first and ex-nuptial births which have been adjusted to allow for a slight ageing of the mothers of these births. It has been assumed that the distributions of ex-nuptial and nuptial first birth order

fertility will continue to change at an exponential rate from their patterns in 1983 to new patterns in 1988, at the rate of change observed between 1980-81 and 1982-83. The patterns determined for 1988 are assumed to prevail thereafter. The effect of these variations is presented in Table 4.5, which shows that the median ages of mothers of ex-nuptial and first order births are projected to rise from 22.9 years and 26.1 years in 1983 to 23.3 years and 26.7 years in 1988 respectively.

The derived age-specific fertility rates for each projection year from 1984 to 2021 are given in Table 4.1. It is clear that for the projection years the level, as well as the proportion (of total fertility) of age-specific fertility rates in the age-groups 15-19, 20-24 and 35-39 to 45-49 should continue to decline, whereas the opposite is true for the rates in the age groups 25-29 and 30-34. This is consistent with the time-trend analysis of past fertility rates.

The median age of mothers at birth of child which has shown a rising trend in the past, should increase from its level of 27.2 years in 1983 to 27.4 in 1987 and is assumed to remain at that level thereafter (Table 4.2).

TABLE 4.5 DISTRIBUTION OF EX-NUPTIAL AND NUPTIAL FIRST BIRTH ORDER FERTILITY RATES BY AGE, AUSTRALIA, 1980, 1983 AND 1988

Year	Age of women							Total	Median age
	15-19	20-24	25-29	30-34	35-39	40-44	45-49		
EX-NUPTIAL BIRTHS									
1980	32.4	34.5	18.4	9.4	4.1	1.1	0.1	100.0	22.6
1983	29.8	34.5	20.7	10.1	3.9	0.9	0.1	100.0	22.9
1988	27.0	35.0	23.1	11.7	3.4	0.7	0.1	100.0	23.3
NUPTIAL FIRST ORDER BIRTHS									
1980	7.9	38.5	37.5	12.4	3.2	0.5	0.0	100.0	25.5
1983	5.8	35.6	39.9	14.4	3.7	0.6	0.0	100.0	26.1
1988	3.7	31.0	44.3	18.8	4.4	0.8	0.0	100.0	26.7

#### 4.1.8 State and Territory variations in fertility

Fertility in all States and Territories declined during 1971 to 1983. However, the levels achieved in 1971 and the levels reached in 1983 differ (Figure 4.2). Overall, during 1971 to 1983 South Australia and Victoria had lower levels, and Queensland, Tasmania and the Northern Territory higher levels, than the average for

FIGURE 4.2 TOTAL FERTILITY RATES, STATES AND TERRITORIES, 1971 TO 1983

Australia. Fertility levels in the remaining States and the Australian Capital Territory have been around the Australian average (Figure 4.2). The level of fertility in the Northern Territory is still much higher than the Australian average, largely because of high Aboriginal fertility.

The TFR for South Australia, which remained consistently lower than the Australian average for all of the period, appeared to be converging to the Australian level in 1983, whereas that of Victoria appeared to be diverging from it, although the difference is small. Fertility differences between Queensland and Australia also appeared to be widening.

Table 4.6 presents the relative position of each State and Territory in terms of fertility indicators for 1983. It can be seen that the States not only vary in terms of the TFR recorded in 1983, but that they also differ in the rates, in the contribution to total fertility of ex-nuptial and nuptial fertility, in median ages of the mothers of births of various birth orders, and in the age patterns of fertility.

Table 4.7 presents the average number of children ever born to all women for each State and Territory and Australia as revealed by the 1981 Census. The average parity of women aged under 35 reveals fertility differentials between the States and Territories similar to those mentioned previously. Whether such observed variations will disappear or will persist in the future can only be a matter of speculation, but in the short-term, for the purpose of the population projections, these variations have been taken into account.

#### 4.1.9 Fertility projections for the States and Territories

Having regard to the existing fertility differentials between the States and Territories, two assumptions for future fertility levels have been made:

- I - in the next five years the current levels of the total fertility rate in New South Wales, Western Australia, Tasmania and the Australian Capital Territory will progressively merge to equal the Australian total fertility rate by 1989. At the same time, there will be a gradual decline in total fertility in the Northern Territory and by 1989 its projected level will be 10 per cent higher than the average figure for Australia. Queensland will be 5 per cent higher and Victoria and South Australia 5 per cent lower than the Australian fertility level in 1989. Such differentials having been established by 1989, will continue in the future,
- II - after 1989, the State differentials will progressively merge, and from 1995 onwards all the States and Territories will have the same fertility level as Australia, illustrating the long-term effect of fertility at replacement level on population size.

Table 4.8 shows projected total fertility rates for the States and Territories.

TABLE 4.7 AVERAGE NUMBER OF CHILDREN BORN TO ALL WOMEN 15 YEARS AND OVER BY AGE, STATES AND TERRITORIES, 1981

Age	NSW	VIC	QLD	SA	WA	TAS	NT	ACT	AUSTRALIA
15-19	0.07	0.05	0.09	0.06	0.07	0.10	0.24	0.04	0.07
20-24	0.46	0.39	0.53	0.43	0.48	0.59	0.73	0.37	0.46
25-29	1.26	1.22	1.41	1.23	1.35	1.49	1.42	1.18	1.28
30-34	1.97	2.01	2.13	1.96	2.08	2.20	2.16	1.93	2.02
35-39	2.37	2.47	2.56	2.38	2.49	2.64	2.58	2.34	2.45
40-44	2.70	2.81	2.93	2.78	2.88	3.02	3.14	2.69	2.80
45-49	2.87	2.98	3.16	3.01	3.13	3.22	3.56	2.92	2.99
50-54	2.84	2.94	3.11	2.99	3.16	3.22	3.56	2.91	2.96
55-59	2.68	2.77	2.96	2.85	2.99	3.08	3.33	2.85	2.80
60-64	2.58	2.63	2.81	2.65	2.85	2.92	3.31	2.74	2.67
65-69	2.46	2.47	2.68	2.47	2.70	2.75	3.05	2.72	2.53
70+	2.44	2.35	2.59	2.32	2.62	2.68	3.21	2.58	2.45
Total	1.97	1.98	2.11	1.98	2.05	2.18	2.02	1.84	2.01

The age pattern of fertility of all births within each State and Territory ideally should be determined in the same way as has been done for Australia. However, such an exercise does not make much difference to the projected births, is laborious and was therefore not undertaken. Instead, the age patterns of fertility (all births) as observed in 1983 for each State and Territory is used for this purpose and the projected number of births for the States and Territories are forced to add to the Australian total.

## 4.2 Mortality

### 4.2.1 Introduction

The ABS Occasional Paper No 1983/2 contained a detailed analysis of mortality trends up to 1981 and projections of mortality to year 2020. In summary, the Occasional Paper presented mortality projections on the basis of proposed short-term (1981 to 1985) and long-term (1986 to 2020) rates of decline in the prevailing age-sex mortality rates. This resulted in the projection of slightly faster rates of decline in mortality than those used in the previous ABS projections produced in 1982.

(a) per 1,000 women

The rationale for such an approach came from the fact that mortality rates at nearly all ages declined more rapidly in the last decade than the average long-term rate of decline. As a consequence, it seemed likely that similar rates of decline would prevail in the near future, but it was doubtful whether such high rates could persist in the longer term. The projections therefore allowed for a continuation of relatively high rates of decline for a short period followed by a period of relatively less decline in mortality.

This section reviews the more recent trends in mortality to determine whether the previous assumptions have been appropriate, and provides a revised set of mortality rates for the current series of population projections.

#### 4.2.2 Recent mortality experience

In 1982 there was an increase in the number of deaths and in mortality rates: there were 5,768 more deaths (2,599 male and 3,169 female) than in 1981. The expectation of life at birth dropped between 1981 and 1982 from 71.36 to 71.22 years for males and from 78.42 to 78.19 years for females. Mortality increased at almost all age groups. All States and Territories had an increase in their levels of mortality. This increase in deaths during 1981-82 was substantially a result of the rise in deaths caused by 'diseases of the circulatory system' (425 male and 1,216 female), 'diseases of the respiratory system' (996 male and 579 female) and 'neoplasms' (448 males and 579 female). In proportionate terms, the largest increase took place among deaths caused by the diseases of the respiratory system. The increases in deaths and death rates due to neoplasms have been consistent with past trends.

In 1983 however, mortality declined again to levels less than those of 1981 for both males and females. The expectation of life at birth in 1983 was 72.09 for males and 78.72 for females.

It appears therefore, that the increase in death rates in 1982 was temporary and not consistent with longer term trends.

#### 4.2.3 Mortality projections for Australia

Notwithstanding the increase in the 1982 mortality level, the trends on which the mortality projections presented in the Occasional Paper were based are likely to continue to be appropriate for the future. However, the short-term rates of decline have been extended to 1987 while the long-term rates of decline apply up to 1995 only (Table 2.3). Beyond 1995, no further decrease in mortality rates is assumed, as the projected expectation of life at birth for both males and females in 1995, 73.5 for males and 80.2 for females, is higher than that currently observed in any country. These projected life expectancies are consistent with those accepted by the United Nations for their population projections (United Nations, 1982(2)).

#### 4.2.4 Mortality projections for the States and Territories

In the previous projections (Catalogue No. 3214.0) the mortality rates for the States and Australian Capital Territory were assumed to be the same as for Australia in each year from 1981 to 2021. For the Northern Territory the mortality experience for the three

years 1978 to 1980 was assumed to merge to the projected Australian level by 1990.

Although the mortality differentials between the States and Territories have narrowed considerably from those that existed in the early 1900s, the mortality trends over the past twelve years reveal that the assumption of uniform mortality across all States and the Australian Capital Territory into the near future merits further consideration. Table 4.9 gives the standardised death rates for the States and Territories and their ratios to the standardised death rates for Australia for the period 1971 to 1983. It can be seen that, except for the Northern Territory where mortality is much higher than the national average, rates for all other States are within a narrow range of the national rate. Nevertheless, Tasmania and New South Wales have maintained slightly higher levels while South Australia and Western Australia have had levels slightly lower than the Australian average.

For the current series of population projections, the State and Territory age-sex-specific mortality rates as observed in 1981 to 1983 have been reduced for each year up to 1995 according to the short-term and long-term rates of mortality decline given in Table 2.3. No convergence of the State and Territory mortality differentials is assumed.

Some mortality indicators for the States and Territories are given in Table 4.10.

### 4.3 Overseas migration

#### 4.3.1 Introduction

Since 1947, the contribution to Australia's population growth made by overseas migration has been close to 40 per cent of the total growth. However, this contribution has been far from steady and annual net migration gains have fluctuated widely.

In this section recent trends in net migration gain are analysed in terms of the components, the age and sex composition and the distribution by State and Territory, as background to the selection of alternative assumptions for future overseas migration.

#### 4.3.2 Trends in net migration components

The volume of settler arrivals has been the major influence on Australia's net migration gain, although fluctuations in the number of permanent departures of former settlers have also had an impact (Figure 4.3). In line with the increase in the number of settler arrivals in the preceding years, departures of former settlers rose in the mid to late 1960s. At the same time, the number of 'other' Australian residents departing permanently also increased but this outflow appeared to have stabilized in the 1970s.

Table 4.11 presents average annual migration flows for periods since July 1961. This table indicates a number of important shifts in the patterns of migration flows in the past few years. In the period 1961 to 1976, changes in settler intake were generally accompanied by a similar change in net migration gain. In subsequent years, this pattern has been greatly affected by a decline in the number of settler departures, and a substantial

gain due to net long-term movement of residents and visitors.

In summary, the trends in the overseas movements indicate that any assumptions about future levels of net migration will necessarily need to be based on the expected levels of the permanent movement, in particular the number of settler arrivals.

The long and short-term movement of residents and overseas visitors will also affect the actual net migration gain. However, this effect is uncertain in both its magnitude and direction.

#### 4.3.3 Determinants of immigration

Government policies in relation to immigration remain the most important determinants of net migration gain. With the exception of New Zealand citizens, all non-Australian citizens require the Government's approval to gain admission to and to reside in Australia.

Governments have controlled the volume of migration through policies in relation to granting of assisted passages, the acceptance of refugees, selection of migrants in relation to occupational, economic and other characteristics, support for the concept of family reunions, etc.

Economic conditions in Australia influence Government policies in relation to the rate of inflow of settlers. Consequently, favourable economic conditions in Australia have often been associated with higher levels of immigration. In addition, economic conditions in Australia relative to other countries can affect the other components of net migration, namely movements of Australian citizens or residents and New Zealand citizens. For instance, in the 1950s and 1960s the favourable economic conditions in Europe partially contributed to the return of many former settlers to their countries of origin. In addition, movement between Australia and New Zealand is responsive to the changing relative economic performances of the two countries.

With Government policies and economic conditions the major determinants of the level of immigration, there is a wide range of possible outcomes in the medium to long-term.

#### 4.3.4 Assumed levels of net overseas migration

Historically the level of net overseas migration has fluctuated a great deal. The preliminary figure for 1983-84 suggests a net intake of 46,500 permanent and long-term migrants. In view of this, a level of 50,000 net intake of migrants for each year to 1987, is considered suitable. The two assumptions about levels beyond 1987 are based on:

- I - the average net gain over the past 20 years (approximately 75,000),
- II - the maximum average net gain experienced over a period of years (approximately 100,000).

#### 4.3.5 Age and sex composition of overseas migrants

Permanent movement, as discussed above, remains the most important determinant of net overseas migration gain. Whilst the number of permanent arrivals has fluctuated greatly since 1961, the age composition of this movement has remained relatively stable, even when periods of high migration intake are compared with periods of low intake. The number of permanent departures, although considerably fewer than the number of arrivals, has also shown some fluctuation over the past 20 years. However, the age composition of this movement has remained relatively stable (Table 4.12 and Figure 4.4). The age composition of permanent migrants (separately for arrivals and departures) of recent years (i.e. the average for the three years 1981 to 1983) has been used therefore as the age composition of the projected number of overseas migrations.

FIGURE 4.4 OVERSEAS MIGRATION BY AGE, SELECTED YEARS

Total	100	100	100	100	100	100	100	100

Table 4.12 shows that since 1961 the proportion of males has ranged from 48 per cent to 54 per cent for arrivals, and from 50 per cent to 53 per cent for departures. However, in more recent years, the proportion of males has been close to 52 per cent for arrivals and 50 per cent for departures. The sex composition of the past three years has been used for the whole of the projection period.

#### 4.3.6 State and Territory distribution of overseas migration

Table 4.13 presents the distribution of overseas settlers by State and Territory from two different data sources - overseas arrival and departure statistics and the population census. These distributions are strictly not comparable as the former is obtained from flow data on arrivals of migrants and the latter from stock data which allows for subsequent movement and mortality of migrants between the date of arrival in Australia and the census date. Despite this limitation, there is a broad agreement in the

TABLE 4.13 PERCENTAGE STATE AND TERRITORY DISTRIBUTION OF PERMANENT OVERSEAS MIGRATION, SELECTED YEARS

State or Territory	Based on census data - Persons whose usual residence 5 years ago was overseas			Overseas arrival and departure statistics				Projected

distribution of overseas migrants settling in each State and Territory. It has been assumed, therefore, that the projected distribution will continue the time-trend exhibited by these data in the past with only minor modification to the shares for New South Wales, South Australia and Western Australia.

As previously discussed, permanent departures are partially related to the number of settler arrivals in previous years. Consequently, in the long run, the State or Territory of origin of departures is assumed to approximate the State or Territory of arrival of settlers. The projected distribution by State and Territory of permanent arrivals has therefore been used for permanent departures for the entire projection period.

#### 4.4 Interstate migration

##### 4.4.1 Introduction

The level of net interstate migration has an important influence on the distribution of Australia's population between the States and Territories. It has historically been much more important than differential fertility or mortality and in many periods more important than overseas migration.

In this section past trends in interstate migration are presented as background to the assumptions for the population projections.

##### 4.4.2 Trends in interstate migration

Table 4.14 presents five-yearly gross and net interstate migration flows as recorded by the Censuses of 1971, 1976 and 1981. Table 4.15 presents the annual gross and net migration flows for 1975-76 and 1980-81 derived from the 1976 and 1981 Censuses, and estimates for 1981-82 and 1982-83 calculated for the estimated resident populations series.

The pattern of net interstate migration has been one of consistent loss from New South Wales, Victoria and to a lesser extent from Tasmania, and consistent net gain for Queensland, Western Australia and Northern Territory. South Australia has generally recorded a net loss apart from the period 1971 to 1976, while the Australian Capital Territory had a period of high net gain from 1966 to 1976 but has now stabilized to smaller fluctuating gains and losses.

The total gross flow indicates a peak in mobility in 1981-82. Departures from all States followed this pattern but peaked one year earlier in the two Territories. Apart from the Australian Capital Territory, the same pattern is also evident in arrivals. In the Australian Capital Territory, arrivals have been declining steadily for the past few years.

When net movement between individual States and Territories is examined, some obvious patterns emerge:

##### New South Wales:

there have been consistent net losses to Queensland, Western Australia and Northern Territory, offset in part by consistent net gains from Victoria. Movement between New South Wales and Australian Capital Territory has fluctuated in the last few years, with small net gains in 1980-81 and 1981-82 and a small net loss in 1982-83;

**Victoria:**

there have been consistent net losses to all States and Territories apart from South Australia and Tasmania which have provided small net gains in the last two years;

**Queensland:**

there have been consistent net gains from all States and Territories in the last decade with over 80 per cent coming from New South Wales and Victoria;

**South Australia:**

there have been consistent net losses in the last seven years to all States and Territories, particularly Queensland, Northern Territory and Victoria;

**Western Australia:**

there have been net gains from all States and Territories, except Queensland and Northern Territory;

**Tasmania:**

there have been consistent but small net gains from New South Wales, with major losses in recent years to Queensland, Victoria and Western Australia;

**Northern Territory:**

there have been consistent net gains from all States and Territories except Queensland, the major source being South Australia;

**Australian Capital Territory:**

there have been high net gains from all States and Territories in the period 1966 to 1976, followed by consistent gains from Victoria, South Australia and Tasmania, offset by losses to Queensland and Northern Territory. Net movement between New South Wales has fluctuated.

**4.4.3 Projected illustrative levels of net interstate migration**

In the light of the foregoing and having regard to information provided by population experts consulted in each State, two assumptions for net interstate migration were selected. These projected levels are given in Table 2.5 of Section 2.

**4.4.4 Age and sex composition of interstate migrants**

The percentage age distributions of interstate arrivals and departures recorded for 1975-76 and 1980-81 by the 1976 and 1981 Censuses are illustrated in Figure 4.5. These show a drop in the propensity to move interstate as children pass through their teens, followed by a steep rise to the most mobile time of life, the twenties. From there, the proportion moving interstate declines steadily with age (reflecting in part the smaller proportion of people in the population at the higher age groups) reaching its lowest level in the fifties. There is a slight rise, especially for females (because there are more females than males in the population) after age 60.

There is also a typical life-cycle pattern of sex differentials evident in interstate arrivals and departures for all States and Territories. This is highlighted by the characteristic peak for

female movers at ages 20-24 compared with the wider peak age range for males of 20-29.

Exceptions to these generalisations are evident in some States and Territories. For example, the proportion of females moving interstate did not exceed males in the 15-19 age group in Victoria (arrivals and departures in 1980-81) and Western Australia (departures in 1975-76 and 1980-81). The upward swing in mobility after age 60 was not evident in the Northern Territory in 1975-76. Further examples of differentials can be seen in Figure 4.5 by comparing peak mobility levels - the highest being in Western Australia and the Northern Territory and the lowest in Queensland - as well as the other turning points at ages 10-14 and 60-64.

A comparison between data for 1975-76 and for 1980-81 reveals certain differences, especially in the proportion moving interstate at ages 1-4 and 20-49, but these are largely due to changes in the age structure of the population. For example, fewer children in the population, as a result of lower birth rates, led to a lower proportion of interstate movers in the 1-4 age group in 1980-81. The differences noted, moreover, are only incidental to the overriding consistency between the age-sex patterns for these two years.

Table 4.16 shows the masculinity ratios (number of males per 100 females) of interstate arrivals and departures for all States and Territories in the periods 1966 to 1971, 1971 to 1976, 1976 to 1981, 1975-76, and 1980-81. The data are derived from the 1971, 1976 and 1981 Censuses and exclude 0-4 year old children in the five-yearly intervals, and children under 1 year of age in the one-yearly intervals.

There is consistency in these masculinity ratios at the national level for the two groups - for the five-yearly periods the ratio is 106-107 and for the twelve-monthly periods the ratio is 110-111. Ratios for the twelve-monthly periods are higher than the five-yearly because the latter exclude a higher proportion of multiple interstate moves which are generally dominated by male movers.

Some of the more notable trends which emerge at the State and Territory level are the high masculinity ratio of interstate movement to and from the Northern Territory and Western Australia and the low masculinity ratio of movement to and from Tasmania and to the Australian Capital Territory.

The age-sex distributions of interstate arrivals and departures are also estimated by the ABS for its population estimation. This series is based on up-to-date information on the interstate movement of children aged under 15, for whom family allowance is paid, the relationship of movers under 15 to those aged 15 and over as recorded at the latest census, and the internal migration survey. It provides even more consistent age-sex distributions of interstate migrants. These distributions for 1982 and 1983 have been used in the current series of population projections for splitting assumed total interstate migrants into arrivals and departures by sex and age.
